ABSTRACT

Context. The Kilo-Degree Survey (KiDS) is an optical wide-field imaging survey carried out with the VLT Survey Telescope and the OmegaCAM camera. KiDS will image 1500 square degrees in four filters (*ugri*), and together with its near-infrared counterpart VIKING will produce deep photometry in nine bands. Designed for weak lensing shape and photometric redshift measurements, its core science driver is mapping the large-scale matter distribution in the Universe back to a redshift of ~ 0.5 . Secondary science cases include galaxy evolution, Milky Way structure, and the detection of high-redshift clusters and quasars.

Aims. KiDS is an ESO Public Survey and dedicated to serving the astronomical community with high-quality data products derived from the survey data. Public data releases, the first two of which are presented here, are crucial for enabling independent confirmation of the survey’s scientific value. The achieved data quality and initial scientific utilization are reviewed in order to validate the survey data.

Methods. A dedicated pipeline and data management system based on ASTRO-WISE, combined with newly developed masking and source classification tools, is used for the production of the data products described here. Science projects based on these data products and preliminary results are outlined.

Results. For 148 survey tiles (≈ 160 sq.deg.) stacked *ugri* images have been released, accompanied by weight maps, masks, source lists, and a multi-band source catalogue. Limiting magnitudes are typically 24.3, 25.1, 24.9, 23.8 (5σ in a $2''$ aperture) in *ugri*, respectively, and the typical *r*-band PSF size is less than $0.7''$. The photometry prior to global homogenization is stable at the $\sim 2\%$ (4%) level in *gri* (*u*) with some outliers due to non-photometric conditions, while the astrometry shows a typical 2D rms of $0.03''$. Early scientific results include the detection of nine high-*z* QSOs, fifteen candidate strong gravitational lenses, high-quality photometric redshifts and structural parameters for hundreds of thousands of galaxies.

Key words. methods: observational – surveys – galaxies: general – large-scale structure of Universe

1. Introduction

Sensitive, wide-field astronomical surveys have proven to be extremely useful scientific resources, not only for the specific scientific use cases they are designed for, but also due to their legacy value and as source-finders for the largest telescopes. With the arrival of VISTA in 2010 and the VLT Survey Telescope (VST) in 2011, the European astronomical

community now has access to dedicated survey telescopes both in the infrared and the optical. During the first years of operations the majority of observing time on both telescopes is dedicated to a number of public surveys, large observational programs selected by ESO that serve the astronomical community with regular public data releases¹. On VST these are the

¹ <http://www.eso.org/sci/observing/PublicSurveys.html>

VST Photometric H- α Survey of the Southern Galactic Plane (VPHAS+, [Drew et al. 2014](#)), VST ATLAS ([Shanks et al. 2013](#)), which covers 5000 square degrees in the Southern Galactic Cap to similar depth as the Sloan Digital Sky Survey (SDSS, [Ahn et al. 2012](#)), and the Kilo-Degree Survey (KiDS, [de Jong et al. 2013](#)). The Kilo-Degree Survey (KiDS) is the largest public survey on the VST in terms of observing time and will image 1500 square degrees of extragalactic sky in four filters, u , g , r , and i . Together with the VISTA Kilo-Degree Infrared Galaxy Survey (VIKING, [Edge et al. 2013](#)), a sister survey on VISTA that observes the same area in Z , Y , J , H and K_S , this will result in a deep nine-band data set with, in total, 185 min of observing time per survey tile over all filters. Part of a long heritage of ever improving wide-field optical sky surveys, the combination of superb image quality with wide wavelength coverage provided by KiDS/VIKING will be unique for surveys of this size and depth for the foreseeable future.

The main science driver for KiDS is mapping of the large-scale mass distribution in the Universe and constraining its expansion history by means of weak gravitational lensing and photometric redshift measurements. These goals put stringent requirements on image quality and stability, photometric depth and calibration accuracy. However, this high data quality will be beneficial for many other science cases, and secondary science drivers for KiDS include a varied set of topics, such as the evolution of clusters and galaxies, galaxy scaling relations, Galactic stellar halo structure, and searches for rare objects such as strong gravitational lenses and high-redshift quasars. How KiDS will benefit the primary and secondary science drivers is discussed in more detail in [de Jong et al. \(2013\)](#).

KiDS data will be released to the astronomical community in yearly Public survey releases of those survey tiles that have been observed in all four filters. In this paper we describe the data products of the first two such KiDS data releases (DR), covering a total of 148 survey tiles. Apart from the released data products (Sect. 2), observational set-up (Sect. 3), the data processing pipeline (Sect. 4) and data quality (Sect. 5), we also review the scientific research that is currently being carried out by the KiDS team using the data presented here in Sect. 6. Finally, the paper is closed with a brief summary and outlook in Sect. 7.

2. Data description

2.1. General properties

KiDS is designed for weak lensing shape and photometric redshift measurements, with weak gravitational lensing tomography as its ultimate science goal. This goal is efficiently reached at the VST with deep, good-seeing r -band observations taken under the best atmospheric conditions, supplemented with somewhat shallower and less sharp u , g , i images. Galaxy shapes for the lensing studies can then be measured on the r band data, while the other bands yield colours that can be used to derive photometric redshifts for these same galaxies. The detailed implementation of these requirements is described below in Sect. 3; typical values for the resolution (PSF FWHM) and limiting magnitude (5σ AB magnitude in a $2''$ aperture) are ($1.0''$, $0.8''$, $0.65''$, $0.85''$) and (24.3, 25.1, 24.9, 23.8) in u , g , r and i bands, respectively (see Sect. 5 for a detailed description). The i band data are significantly less uniform in quality than the other bands because they are mostly taken when the moon is above the horizon.

2.2. OmegaCAM and VST

Designed to provide superb and uniform image quality over the full field-of-view (FOV), the combination of VST and the OmegaCAM wide-field imager is ideal for a survey such as KiDS. The VST, an alt-az mounted modified Ritchey-Cretien telescope, uses a two-lens field corrector and has active primary and secondary mirrors. OmegaCAM is a 268 Megapixel CCD imaging camera with a one square degree FOV. Located at the Cassegrain focus, it is the only instrument on the VST. The filters and dewar window are part of the total optical design, with the latter acting as a field lens. The science array consists of 32 thinned, low-noise $2k \times 4k$ E2V devices. With little aberration over the full FOV the 15μ pixel size translates to a constant pixel scale of $0.21''$ with small gaps of $25''$ and $85''$ between the CCDs. Wavefront sensing, using two auxiliary CCDs on either side of the science array, is employed to monitor and optimize the optical set-up in real time. Auto-guiding of tracking and rotation makes use of two more auxiliary CCDs. Combined, the VST and OmegaCAM provide a point spread function (PSF) equal to the atmospheric seeing over the full FOV down to $0.6''$. More details on the VST and OmegaCAM can be found in [Capaccioli et al. \(2012\)](#) and [Kuijken \(2011\)](#), respectively.

2.3. Sky distribution

KiDS data releases consist of ~ 1 square degree tiles that have been successfully observed in all four survey filters (u, g, r, i). To maximize the synergy with existing spectroscopic surveys and between KiDS and VIKING early on, the latter surveys both prioritize the observations in the Galaxy And Mass Assembly (GAMA, [Driver et al. 2011](#)) fields G9, G12, G15 and G23.

The first public data release of KiDS (KiDS-ESO-DR1) was issued in July 2013 and contains imaging data, masks and single-band source lists for all tiles observed in all four filters during the first year of regular operations (15 October 2011 to 31 September 2012), including data taken during Early Science Time (EST, 13 August to 15 October 2011), a total of 50 tiles. The second data release (KiDS-ESO-DR2) was available in February 2015 and contains the same data products for all tiles for which observations were completed during the second year of regular operations (1 October 2012 to 31 September 2013), a total of 98 tiles. Since the processing pipeline used for KiDS-ESO-DR2 is practically identical to that used for KiDS-ESO-DR1, the tiles released in the former complement the data set of the latter, making KiDS-ESO-DR2 an incremental release. Apart from the data products mentioned above, KiDS-ESO-DR2 also provides a multi-band source catalogue based on the combined set of 148 tiles released in the first two data releases.

Many other fields have been observed in a subset of the filters and will be included in future releases once their wavelength coverage is complete. Figure 1 shows the sky distribution of the tiles included in KiDS-ESO-DR1/2 within the KiDS fields. A complete list of all tiles with data quality parameters can be found on the KiDS website².

2.4. Data products

For every tile in the first two data releases of KiDS the following data products are included for each of the bands, u , g , r , and i :

- astrometrically and photometrically calibrated, stacked images (“coadds”);

² <http://kids.strw.leidenuniv.nl/DR2>

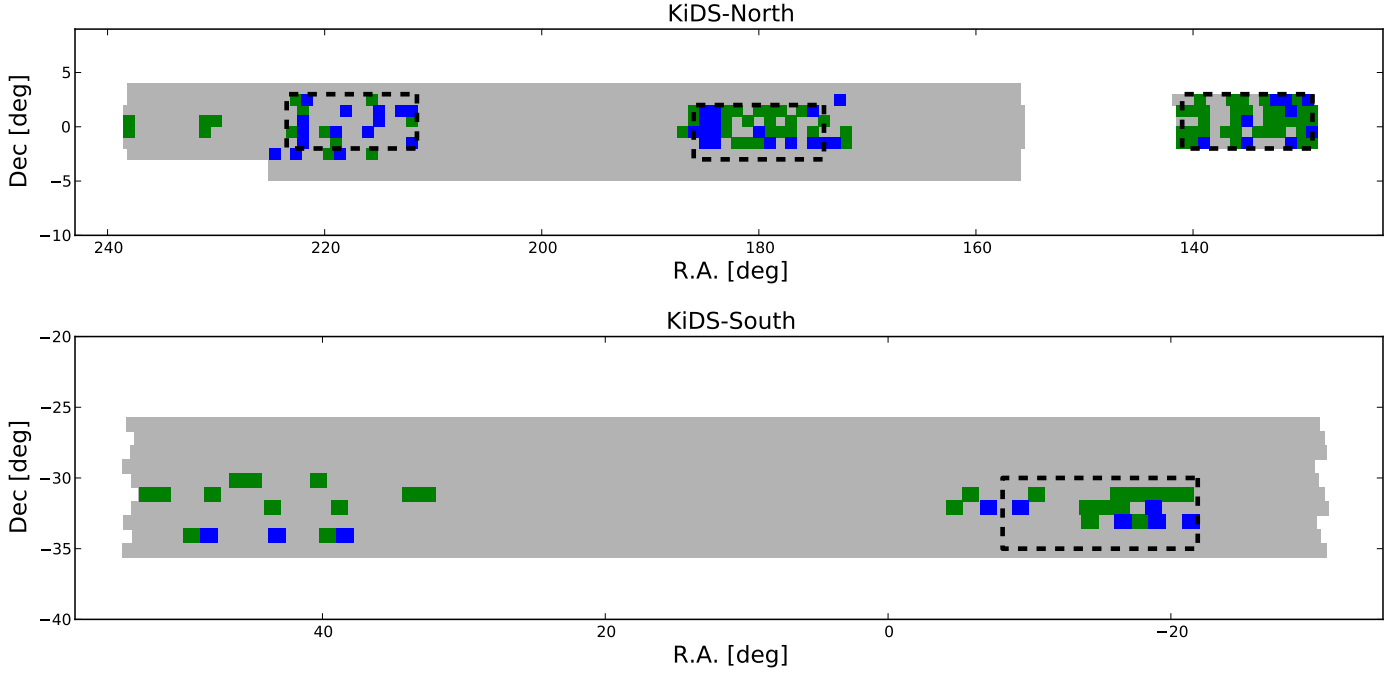

Fig. 1. Sky distribution of survey tiles released in KiDS-ESO-DR1 (blue) and KiDS-ESO-DR2 (green), with the full KiDS area is shown in grey. *Top:* KiDS-North. *Bottom:* KiDS-South. The multi-band source catalogue covers the combined area (blue + green). The black dashed lines delineate the locations of the GAMA fields.

- weight maps;
- flag maps (“masks”) that flag saturated pixels, reflection halos, read-out spikes, etc.;
- single-band source lists.

The multi-band source catalogue encompassing the combined area of the two data releases, although forming one large catalogue, is stored in multiple files, namely one per survey tile.

2.4.1. Coadded image units and gain

The final calibrated, coadded images have a uniform pixel scale of 0.2 arcsec. The pixel units are fluxes relative to the flux corresponding to magnitude =0. This means that the magnitude m corresponding to a pixel value f is given by:

$$m = -2.5 \log_{10} f. \quad (1)$$

The gain varies slightly over the field-of-view because of the photometric homogenization procedure described in Sect. 4.2. An average effective gain is provided online³. An example of a FITS header of a coadded image is also provided online⁴.

2.4.2. Single-band source list contents

For each tile single-band source lists are provided for each of the survey filters. To increase the usefulness and versatility of these source lists, an extensive set of magnitude and shape parameters are included, including a large number (27) of aperture magnitudes. The latter allows users to use interpolation methods (e.g. “curve of growth”) to derive their own aperture corrections or total magnitudes. Also provided is a star-galaxy separation

parameter and information on the mask regions (see Sect. 4.4) that might affect individual source measurements. Details on the production of these source lists, including source detection and other measurements are discussed in Sect. 4.5.1.

Table A.1 lists the columns that are present in the single-band source lists provided in KiDS-ESO-DR1/2. Note that of the 27 aperture flux columns only the ones for the smallest aperture (2 pixels, or 0.4” diameter) and the largest aperture (200 pixels, or 40” diameter) are listed.

2.4.3. Multi-band catalogue contents

KiDS-ESO-DR2 includes a multi-band source catalogue. This catalogue is based on source detection in the r -band images. While magnitudes are measured for all of the filters, the star-galaxy separation, positional, and shape parameters are based on the r -band data. The choice of r -band is motivated by the fact that it typically has the best image quality and thus provides the most reliable source positions and shapes. Seeing differences between observations in the different filters are mitigated by the inclusion of aperture corrections. Details on the production of this catalogue are discussed Sect. 4.5.2 and Table B.1 lists the columns present in the multi-band source lists in KiDS-ESO-DR2.

2.5. Colour terms

The photometric calibration provided in KiDS-ESO-DR1 and KiDS-ESO-DR2 is in AB magnitudes in the instrumental system. Colour-terms have been calculated with respect to the SDSS photometric system.

Aperture-corrected magnitudes taken from the multi-band catalogue were matched to SDSS DR8 (Aihara et al. 2011) PSF magnitudes of point-like sources. For each filter, the median offset to SDSS is first subtracted, rejecting tiles where this offset

⁴ http://kids.strw.leidenuniv.nl/DR2/example_imageheader.txt

Table 1. Data products and file types.

Data product	ESO product category name	File type	TTT ^a
Calibrated, stacked images	SCIENCE.IMAGE	FITS image	sci
Weight maps	ANCILLARY.WEIGHTMAP	FITS image	wei
Masks	ANCILLARY.MASK	FITS image	msk
Single-band source lists	SCIENCE.SRCTBL	Binary FITS table	src
Multi-band catalogue	SCIENCE.SRCTBL	Binary FITS table	src

Notes. ^(a) TTT is the three character string indicating the data product type.

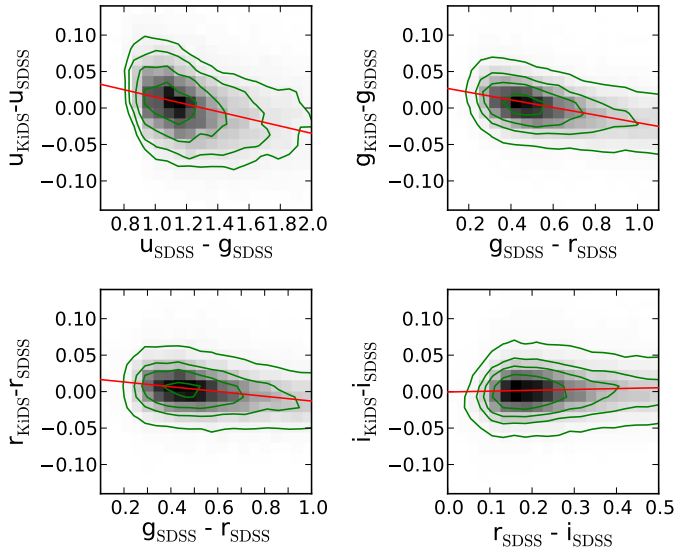

Fig. 2. Derivation of colour-terms of KiDS photometry with respect to the SDSS photometric system. The distribution of stars is shown as a 2D histogram, overlaid with isodensity contours (green) and fit by a linear relation (red line). For u the contours correspond to 50, 100, 200 and 350 stars per bin, and for g , r and i to 100, 350, 600 and 1000 stars per bin. The absolute calibration between KiDS and SDSS (horizontal offset) is arbitrary.

exceeds 0.1 mag in any of the bands (10 tiles), in order to prevent poor photometric calibration to affect the results. The fit is performed on all points from the remaining tiles. Figure 2 shows the photometric comparison and the following equations give the resulting colour terms:

$$u_{\text{KiDS}} - u_{\text{SDSS}} = (-0.050 \pm 0.002)(u_{\text{SDSS}} - g_{\text{SDSS}}), \quad (2)$$

$$g_{\text{KiDS}} - g_{\text{SDSS}} = (-0.052 \pm 0.002)(g_{\text{SDSS}} - r_{\text{SDSS}}), \quad (3)$$

$$r_{\text{KiDS}} - r_{\text{SDSS}} = (-0.033 \pm 0.002)(g_{\text{SDSS}} - r_{\text{SDSS}}), \quad (4)$$

$$i_{\text{KiDS}} - i_{\text{SDSS}} = (+0.012 \pm 0.002)(r_{\text{SDSS}} - i_{\text{SDSS}}). \quad (5)$$

2.6. Data access

Data from the first two KiDS data releases can be accessed in a number of different ways: through the ESO science archive, from the ASTRO-WISE archive, or via a web-based synoptic table on the KiDS website⁵.

2.6.1. ESO archive

As an ESO public survey, the KiDS data releases are distributed via the ESO Science Archive Facility⁶. Using the Phase 3 query

⁵ <http://kids.strw.leidenuniv.nl/DR2>

⁶ <http://archive.eso.org>

forms users can find and download data products such as the stacked images and source lists.

The naming convention used for all data product files in the ESO archive is the following:

KiDS_DRV.V.R.R.D.D_F.TTT.fits,

where V.V is the data release version, R.R and D.D are the RA and Dec of the tile center in degrees (J2000.0) with 1 decimal place, F is the filter (u , g , r , i , or $ugri$), and TTT is the data product type. Table 1 lists the ESO product category name, file type, value of TTT, and an example filename for each type of data product.

For example, the KiDS-ESO-DR1 r -band stacked image of the tile “KIDS_48.3_-33.1” is called KiDS_DR1.0_48.3_-33.1_r_sci.fits, and the KiDS-ESO-DR2 multi-band source list data file corresponding to this tile is called KiDS_DR2.0_48.3_-33.1_ugri_src.fits.

2.6.2. Astro-WISE archive

All data products can also be retrieved from the ASTRO-WISE system (Valentijn et al. 2007; Begeman et al. 2013), the main data processing and management system used for processing KiDS data. The pixel data and source lists are identical to the data stored in the ESO Science Archive Facility, but additionally, the full data lineage is available in ASTRO-WISE. This makes this access route convenient for those wanting to access the various quality controls or further analyse, process or data-mine the full data set instead of particular tiles of interest.

All data products can be accessed through the links provided on the KiDS website via the DBviewer interface. Downloading of files, viewing inspection plots, and browsing the data lineage is fully supported by the web interface.

2.6.3. Synoptic table

A third gateway to the KiDS data is the synoptic table that is included on the KiDS website. In this table quality information on different data products is combined, often in the form of inspection figures, offering a broad overview of data quality.

3. Observational set-up

The KiDS survey area is split into two fields, KiDS-North and KiDS-South, covering a large range in right ascension so that observations can be made all year round. The fields, each approximately 750 square degrees in size, were chosen to overlap with several large galaxy redshift surveys, principally SDSS, the 2dF Galaxy Redshift Survey (2dFGRS, Colless et al. 2001) and the Galaxy And Mass Assembly (GAMA) survey (Driver et al. 2011). KiDS-North is completely covered by the combination of SDSS and the 2dFGRS, while KiDS-South corresponds to the 2dFGRS south Galactic cap region. Four out of five GAMA

Table 2. KiDS observing strategy: observing condition constraints and exposure times.

Filter	Max. lunar illumination	Min. moon distance (deg)	Max. seeing (arcsec)	Max. airmass	Sky transp.	Dithers	Total Exp. time (s)
<i>u</i>	0.4	90	1.1	1.2	CLEAR	4	1000
<i>g</i>	0.4	80	0.9	1.6	CLEAR	5	900
<i>r</i>	0.4	60	0.8	1.3	CLEAR	5	1800
<i>i</i>	1.0	60	1.1	2.0	CLEAR	5	1200

fields lie within the KiDS fields. Figure 1 shows the outline of the survey fields.

Each survey tile is observed in the *u*, *g*, *r*, and *i* bands. Exposure times and observing constraints for the four filters are designed to match the atmospheric conditions on Paranal and optimized for the survey’s main scientific goal of weak gravitational lensing. KiDS makes use of queue scheduling, allowing the data requiring the best conditions to be observed whenever these conditions are met. In order to promote building up full wavelength coverage as quickly as possible, pointings for which a subset of filters has been observed receive higher priority. Unfortunately, the queue scheduling system does not allow prioritizing of survey tiles based on the observational progress of neighboring tiles. As a result, the queued tiles are observed in a random order, resulting in the patchy on-sky distribution visible in Fig. 1. The median galaxy redshift of the final survey will reach 0.7 and the best seeing conditions are reserved for the *r*-band, since this functions as the shape measurement band. Each position on the sky is visited only once in each filter, so that the full survey depth is reached immediately. While this precludes variability studies, it will allow the other science projects to benefit from deep data from the start. During the survey the observing constraints have been fine-tuned to optimize between survey speed and scientific return, and Table 2 lists the limits employed for the majority of the period during which the data presented here were obtained.

Since the OmegaCAM CCD mosaic consists of 32 individual CCDs, the sky covered by a single exposure is not contiguous but contains gaps. In order to fill in these gaps, KiDS tiles are built up from 5 dithered observations in *g*, *r* and *i* and 4 in *u*. The dithers form a staircase pattern with dither steps of 25'' in X (RA) and 85'' in Y (Dec), bridging the inter-CCD gaps (de Jong et al. 2013), see Fig. 3. Although filled in, the gaps result in areas within the footprint that are covered by fewer than 5 exposures, thus yielding slightly lower sensitivity. Due to this dithering strategy the final footprint of each tile is slightly larger than 1 square degree: 61.9×65.4 arcmin in *u*; 62.3×66.8 arcmin in *g*, *r* and *i*. Neighbouring dithered stacks have an overlap in RA of 5% and in Dec of 10%. The tile centers are based on a tiling strategy that covers the full sky efficiently for VST/OmegaCAM⁷. The combination of the tiling and dithering scheme ensures that every point within the survey area is covered by a minimum of 3 exposures.

4. Data processing

The data processing pipeline used for KiDS-ESO-DR1/2 is based on the ASTRO-WISE optical pipeline described in McFarland et al. (2013, henceforth MF13). Below we summarize the processing steps and list KiDS-specific information,

⁷ <http://www.astro.rug.nl/~omegacam/dataReduction/Tilingpaper.html>

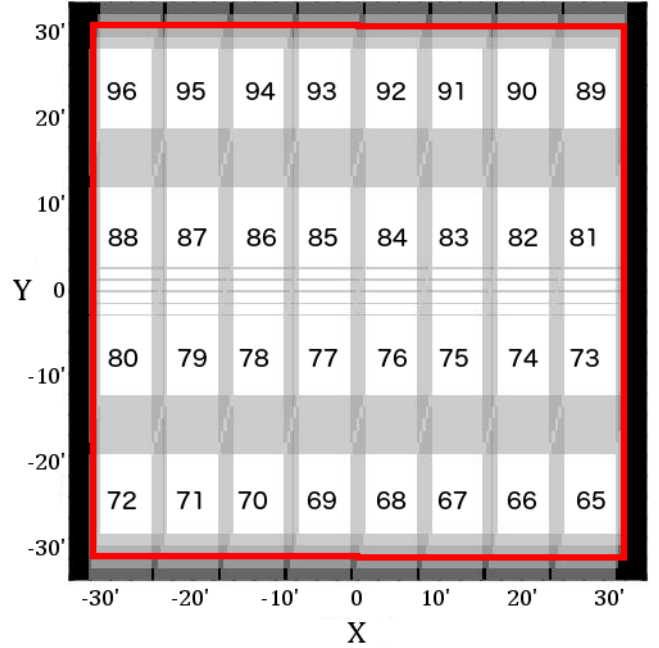

Fig. 3. Tile footprint sky coverage for observations in *g*, *r* and *i*. To fill in the gaps between the CCDs five dither steps are done, yielding a sky coverage pattern where the vast majority of the field-of-view is covered by four or five exposures. White regions are covered by five exposures and increasingly darker shades of gray by four, three, two and one. The numbers 65 to 96 indicate the CCD numbering according to the CCD naming scheme and the red rectangle shows how tiles are cropped while creating the multi-band catalogue.

covering the KiDS process configuration and departures from the ASTRO-WISE optical pipeline.

4.1. Image detrending

The first processing steps are the detrending of the raw data, consisting of the following steps.

Cross-talk correction. Electronic cross-talk occurs between several CCDs, but most strongly between CCDs #93, #94, #95 and #96, which share the same video board (see Fig. 3 for CCD numbering scheme). Cross-talk can be both positive and negative, resulting in faint imprints of bright sources on neighbouring CCDs (Fig. 4). Although the cross-talk is generally stable, abrupt changes can occur during maintenance or changes to the instrumentation.

A correction is made for cross-talk between CCDs #95 and #96, where it is strongest (up to 0.7%). Crosstalk between a pair (“source” and “target”) of CCDs is determined by measuring for each pixel, with a value greater than 5000 ADU in the source CCD, the offset of the same pixel in the target CCD from the median value of all pixels in the target CCD. A straight line is

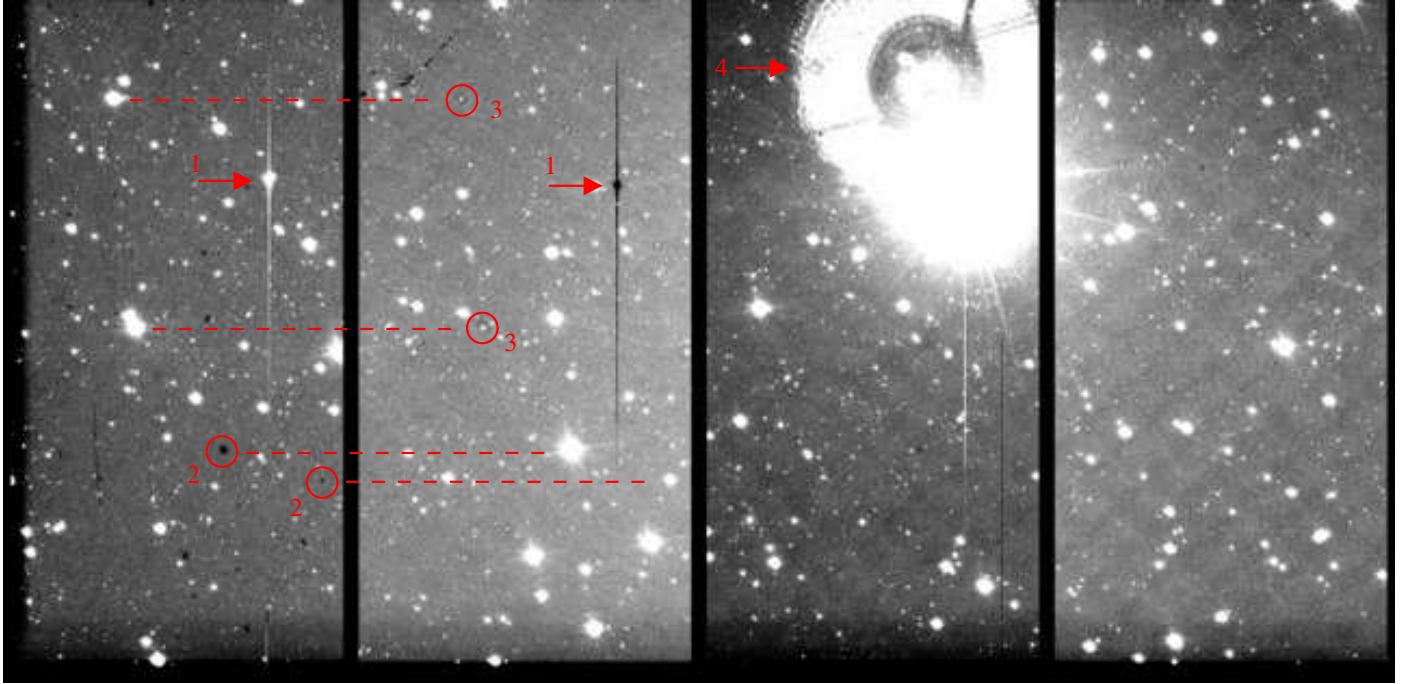

Fig. 4. Example of crosstalk between CCDs 96, 95, 94 and 93 (left to right) of OmegaCAM. Both positive and negative crosstalk due to the bright star in CCD 94 is visible (1). Negative crosstalk on CCD 96 due to bright (saturated and unsaturated) stars on CCD 95 is indicated (2), as well as positive crosstalk on CCD 95 due to bright stars on CCD 96 (3). The bright ring on CCD 94 (4) is an optical “ghost” reflection.

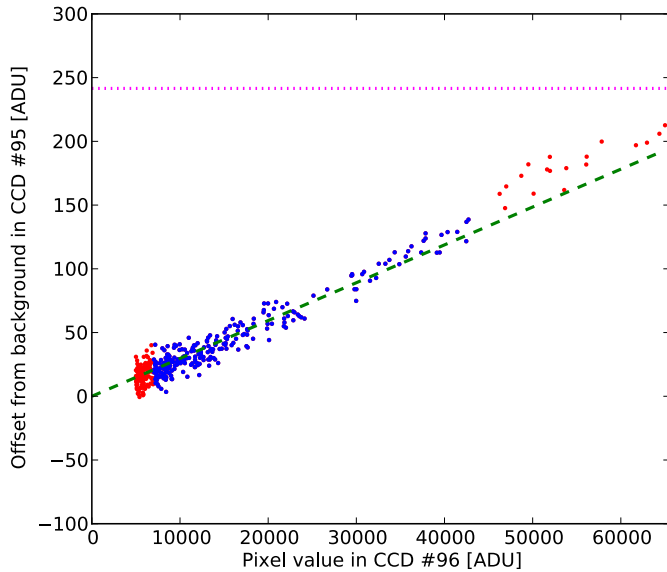

Fig. 5. Measurement of crosstalk between CCDs #95 and #96 for one exposure. A straight line (green dashed) is fit to the offset from the median in the target CCD (here: #95) as a function of signal in the same pixel in the source CCD (here: #96). Only the blue data points are used for this fit since at low ADU levels outliers are often present and at high ADU levels non-linearity affects the measurements. The slope of the green dashed line corresponds to the correction coefficient b . The magenta dotted line shows the constant a value used for saturated pixels.

fit to the trend of this offset as function of the pixel value of the source CCD. See Fig. 5 for an example. The slope of the line (b) is given in Table 3 per stable period. A separate constant is fit to saturated pixels in the source CCD (a in the table). To correct for the crosstalk between CCDs #95 and #96 the correction

factor is applied to each pixel in the target CCD based on the corresponding pixel values in the source CCD:

$$I'_i = \begin{cases} I_i + a, & \text{if } I_j = I_{\text{sat}}, \\ I_i + bI_j, & \text{if } I_j < I_{\text{sat}}, \end{cases} \quad (6)$$

where I_i and I_j are the pixel values in CCDs i and j , I'_i is the corrected pixel value in CCD i due to cross-talk from CCD j , and I_{sat} is the saturation pixel value.

De-biasing and overscan correction. The detector bias is subtracted from the KiDS data in a two step procedure. First, for each science and calibration exposure the overscan is subtracted per row (no binning of rows). For consistency, all science and calibration data are reduced with this same overscan correction method. Second, a daily overscan-subtracted master bias, constructed from ten bias frames and applying 3σ rejection, is subtracted.

Flat-fielding. A single masterflat (per CCD and filter) was used for all data in the release. This is by virtue that the intrinsic pixel

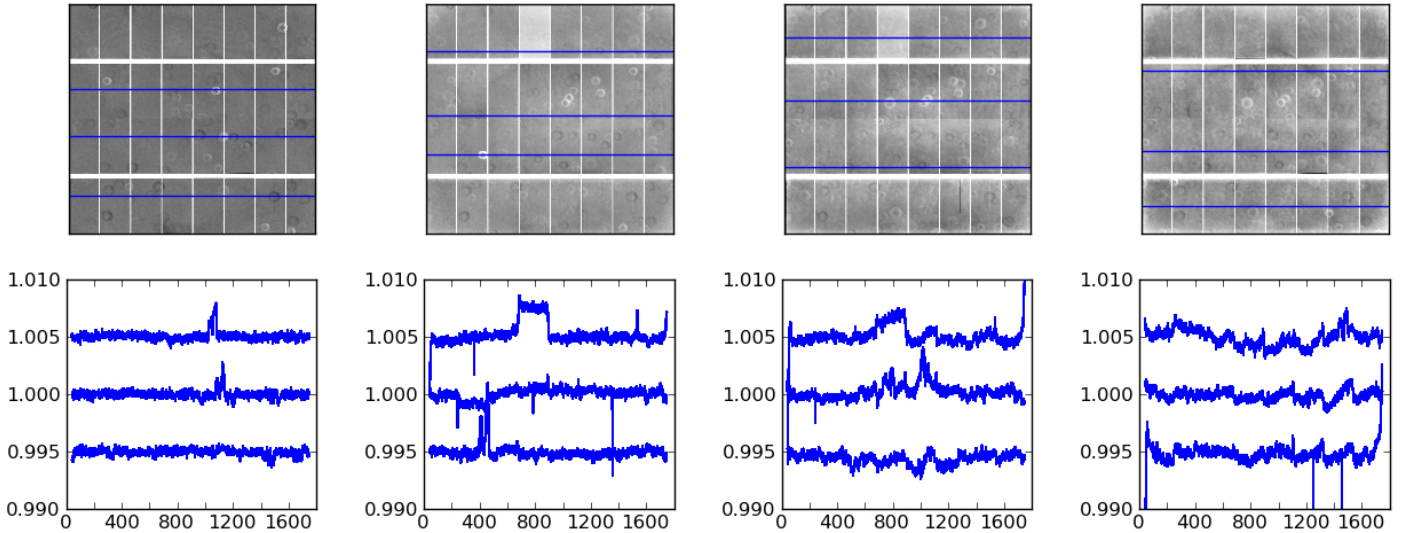

Fig. 6. Dome flat variation over time during the observing period of KiDS-ESO-DR2. The *top panels* show the 10×10 binned dome flat ratios between a dome flat taken on August 7 2011 and, *from left to right*, October 1 2011, April 1 2012, March 2 2013, and November 2 2013. The *bottom panels* show three cuts through the ratio images on top, along the lines indicated in blue on the corresponding top panels. Offsets of -0.005 and $+0.005$ are applied to the bottom and top lines, respectively, to improve legibility.

sensitivities can be considered constant to $\sim 0.2\%$ or better for g , r and i (Verdoes Kleijn et al. 2013). This is illustrated in Fig. 6, where a series of dome flat ratios is shown. The dome flatfields offer the optimal controlled experiment for assessing the pixel sensitivities, as the conditions under which they are observed are closely monitored and calibrated. More specifically, the calibration unit has a special power supply which allows the ramping of the current when switching on and off and the stabilization of the current during the exposure, delivering an exposure level variation less than 0.6% over a period of 1 month (Verdoes Kleijn et al. 2013). The series of ratio plots in Fig. 6 spans the full time period during the KiDS-ESO-DR1/2 observations, demonstrating that the peak-to-valley pixel-to-pixel variations vary less than 0.5% at any time and pixel position.

For g , r and i the master flat is a combination of a master dome (for high spatial frequencies) and master twilight (=sky) flat-field (for low spatial frequencies). Both contributing flats are an average of 5 raw flat-field exposures with 3σ rejection. In u band only the twilight flats are used.

Illumination correction. An illumination correction (also known as “photometric superflat”) is required to correct for illumination variations due to stray light in the flat field images, because of which the flat fields are not a correct representation of the pixel sensitivities and vignetting effects. The illumination correction is applied *in pixel space*, and only on the source fluxes (i.e., after background subtraction). A single illumination correction image is used to correct the single master flats per filter for all data. The correction is determined from observations of several Landolt Selected Area (SA) fields (Landolt 1992) observed at 33 dither positions, such that the same stars are observed with all CCDs. After computing zero-points per CCD the residuals between the measured stellar magnitudes and their reference values sample the illumination variations. Per CCD the illumination correction is characterized to better than 1% . For further details see Verdoes Kleijn et al. (2013).

De-fringing. De-fringing is only needed for the KiDS i -band. Analysis of nightly fringe frames showed that the pattern is constant in time. Therefore, a single fringe image was used for all KiDS-ESO-DR1 images observed after 2012-01-11. For

each science exposure this fringe image is scaled and then subtracted to minimize residual fringes. The general procedure, described in MF13, was modified for the KiDS data in order to take large-scale background fluctuations into account. Some i -band data contain significant background fluctuations even after flatfielding due to scattered light (see Sect. 5.5), which can cause problems with the scaling of the fringe frame. Therefore, background-subtracted science frames were used to determine the scale factor.

Pixel masking. Cosmic-rays, hot and cold pixels, and saturated pixels are automatically masked as described in MF13 during de-trending. These are included in the weight image. Additional automatic and manual masking is then applied on the coadds as described in Sect. 4.4.

Satellite track removal. Satellite tracks are detected by an automated procedure, working on single CCDs, that applies the Hough transform (Hough 1962) to a difference image between exposures with the smallest dither offset. Bright stars and bright reflection halos are masked to limit false detections. The pixels affected by satellite tracks are masked and included in the weight image. Due to the single-CCD approach small sections of satellite tracks in CCD corners may be missed by the algorithm. These remnants are included in the manual masks discussed in Sect. 4.4.

Background subtraction. Many observations show darkened regions at the horizontal CCD edges where the bond wire baffling is placed (Iwert et al. 2006). For KiDS-ESO-DR1/2 this CCD-edge vignetting is corrected by performing a line-by-line background subtraction, implemented as a new background subtraction method during regridding (see Sect. 3.5 of MF13).

The line-by-line background subtraction can be inaccurate if there are not enough ‘background’ pixels on a line, for example nearby bright stars. These regions are identified in the masks.

Non-linearity. The linearity of the response of the OmegaCAM detector-amplifier chain is regularly monitored as part of the VST calibration procedures. No significant non-linearities are present (at the level of $\leq 1\%$ over the full dynamic range of the system), and the pipeline currently does not include a non-linearity correction step.

4.2. Photometric calibration

The steps taken to calibrate the photometry are as follows. The calibration described here is performed per tile and per filter and applied to the pixel data, which is rescaled to the flux scale in Eq. (1).

- Photometric calibration of the KiDS-ESO-DR1/2 data starts with individual zero-points per CCD based on SA field observations (see MF13 for details of the zero-point derivation). The calibration deploys a fixed aperture of 30 pixels ($\sim 6.4''$ diameter) not corrected for flux losses, and uses SDSS DR8 PSF magnitudes of stars in the SA fields as reference. Zero-points are determined every night, except when no SA field observations are available, in which case default values, that were determined in the same way, are used. The total number of tiles for which these default values were used is 16, 13 and 14 in g , r and i , respectively, or $\sim 10\%$ of all tiles. For u the nightly zero-point determinations often show large uncertainties and default zero-points are used more frequently, namely in 112 tiles. Magnitudes are expressed in AB in the instrumental photometric system. No colour corrections between the OmegaCAM and SDSS photometric system are applied.
- Next, the photometry in the g , r and i filters is homogenized across CCDs and dithers for each tile independently per filter. For u -band this homogenization is not applied because the relatively small source density often provides insufficient information to tie adjacent CCDs together. This global photometric solution is derived and applied in three steps:
 1. From the overlapping sources across dithered exposures, photometric differences between the dithers (e.g. due to varying atmospheric extinction) are derived.
 2. Although each CCD was calibrated with its own zero-point, the remaining photometric differences between CCDs are calculated using all CCD overlaps between the dithered exposures. The number of sources in these overlaps can range between a few to several hundreds, depending on the filter and the size of the overlap, and a weighting scheme is used based on the number of sources. Both in steps 1 and 2, photometric offsets are obtained by minimizing the difference in source fluxes between exposures and CCDs using the algorithm of Maddox et al. (1990).
 3. The offsets are applied to all CCDs with respect to the zero-points valid for the night, derived from the nightly SA field observations.

4.3. Astrometric calibration

A global (multi-CCD and multi-dither) astrometric calibration is calculated per filter per tile. SCAMP (Bertin 2006) is used for this purpose, with a polynomial degree of 2 over the whole mosaic. The (unfiltered) 2MASS-PSC (Skrutskie et al. 2006) is used as astrometric reference catalogue, thus the astrometric reference frame used is International Celestial Reference System (ICRS). Using unwindowed positions the external (i.e. with respect to the 2MASS-PSC) and internal accuracies are typically described by a 2D rms of $0.3''$ and $0.03''$, respectively (see also Sect. 5.3). A more detailed description of the astrometric pipeline can be found in MF13.

4.3.1. Regridding and coadding

SWARP (Bertin et al. 2002) is used to resample all exposures in a tile to the same pixel grid, with a pixel size of $0.2''$. After

an additional background subtraction step (using 3×3 filtered 128×128 pixel blocks) the exposures are scaled to an effective zero-point of 0 (see also Sect. 2.4.1) and coadded using a weighted mean stacking procedure. The applied projection method is Tangential, Conic-Equal-Area. Due to the individual photometric offsets applied to the CCDs the gain varies slightly over the coadd. An average effective gain is calculated for each coadd as:

$$\langle G \rangle = N_{\text{exp}} \times \frac{\tilde{G}}{\tilde{S}}, \quad (7)$$

where \tilde{G} and \tilde{S} are the median gain and scale factor of the re-gridded CCD images and N_{exp} is the number of exposures. These average gain values are provided in the online Data table⁸.

4.4. Masking of bright stars and defects

Nearby saturated stars and other image defects are the main source of contamination in the measurement of objects. In KiDS coadds, these features are masked by a stand-alone program, PULECENELLA (v1.0, Huang et al., in prep.). PULECENELLA is a novel procedure for automated mask creation completely independent of external star catalogues. An example of a mask image is shown in Fig. 7.

PULECENELLA detects and classifies the following types of image artifacts resulting from the saturated stars:

- saturated pixels in the core and vicinity of stars;
- spikes caused by diffraction of the mirror supports;
- spikes caused by readout of saturated pixels;
- “ghost” halos produced by the reflections off of optics (up to three wider reflection halos with spatially dependent offsets; these are caused by reflections of different optical elements in the light-path and depend on the brightness of the star).

These features have regular shapes, and scale with the brightness and position of bright stars in a stable way in all images in a given observation band. Hence, PULECENELLA is first configured to model the mask shapes (including the radius of saturation cores, the orientation of diffraction spikes, the size and offset of reflection halos) from some sampled saturated stars; the so configured analytical models are then applied to the batch masking of coadds from the same band. The detection, location and magnitude of saturated stars are derived from a first SEXTRACTOR (Bertin & Arnouts 1996) run over the image to be masked, with a band-specific configuration aiming only for the detection and measurement of the nearly saturated stars; the saturation pixel level is derived from the FITS image header. Thus, PULECENELLA produces star masks specifically for each image, without any dependence on an external star catalogue. This also avoids the ambiguity in the determination of the magnitude cut-off of saturated stars due to the difference between the observed and external catalogue filters.

The position of reflection halos is offset from the center of the host saturated star; the offset can be towards or outward from the image center, depending on the reflection components in the optics. For the primary reflection halo, the offset is first linearly modeled from several primary halos of the brightest stars in the image, and whether the halo mask is applied depends on the brightness of the saturated stars; this brightness level is determined as the number of pixels for which the count level exceeds 80% of the saturation limit and is therefore independent

⁸ <http://kids.strw.leidenuniv.nl/DR2>

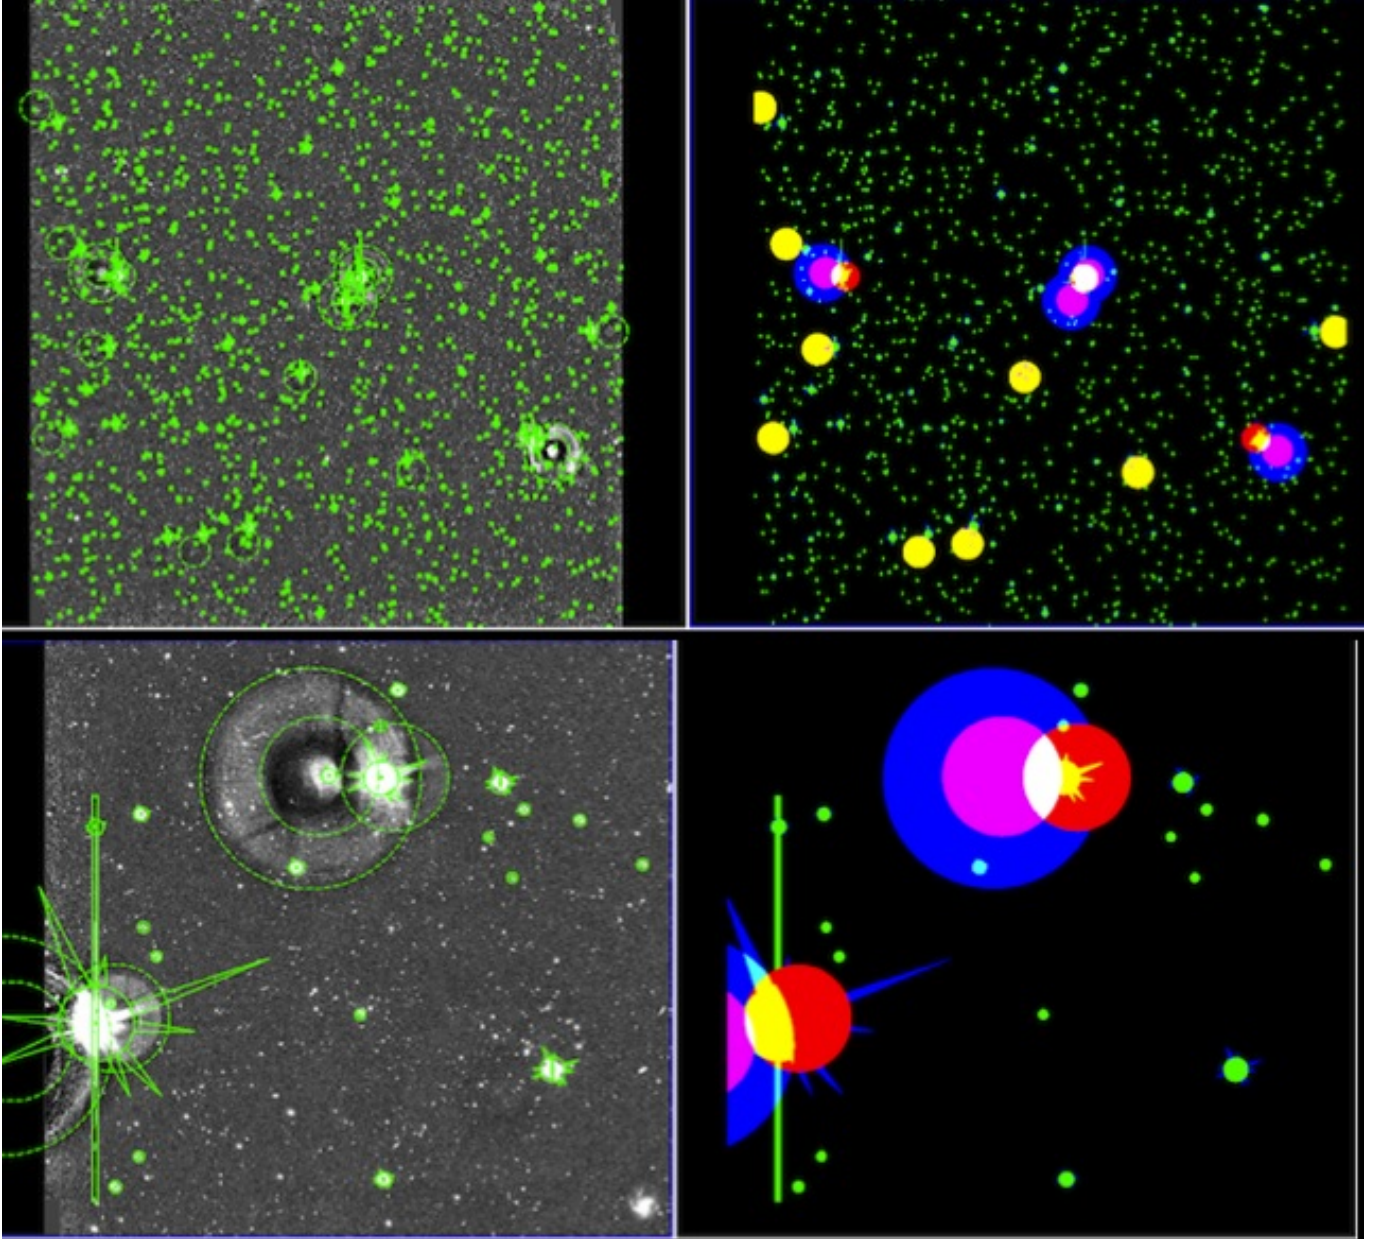

Fig. 7. Examples of a PULECENELLA v1.0 mask. *Top left:* thumbnail of a KiDS stacked image with several bright stars; critical areas detected by PULECENELLA are overplotted with green outlines (region format). *Top right:* FLAG image corresponding to the image shown on the *top left*, with different colours corresponding to the pixel value with the binary flag values summed. *Bottom panels:* as *top panels*, but for a small area in a (different) KiDS stacked image.

of the photometric calibration. The same method is applied for secondary and tertiary halos independently. The details of the masking method are presented in Huang et al. (in prep.).

Besides the analytical star masks, PULECENELLA is also configured to mask pixels in the empty boundary margins, CCD gaps or dead pixels with zero weight. These pixels are flagged as “bad pixels”. Finally, bad regions which are missed by PULECENELLA (e.g. large-scale background artifacts) but are detected by a visual inspection, are manually masked using DS9 and added both to the region file and to the final flag image.

As output, PULECENELLA generates both an ASCII mask region file which is compatible with the DS9⁹ tool and a FITS flag image that can be used in SEXTRACTOR. Different types of masked artifacts/regions are coded with the different binary

values listed in Table 4. In the flag image these binary values are summed.

The flag image is used during source extraction for the single-band source list (see below) to flag sources whose isophotes overlap with the critical areas. The resulting flags are stored in the following two SEXTRACTOR parameters:

- IMAFLAGS_ISO: sum of all mask flags encountered in the isophote profile;
- NIMAFLAG_ISO: number of flagged pixels entering IMAFLAGS_ISO.

Table 5 summarizes the percentages of the total area in KiDS-ESO-DR1/2 that are not masked, masked automatically by PULECENELLA, and manually masked. Due to the lower sensitivity in u the number of saturated stars is much smaller, leading to a

⁹ <http://ds9.si.edu>

Table 4. Critical areas in the masks and their flag values.

Type of area	Flag	Type of area	Flag
Readout spike	1	Secondary halo	16
Saturation core	2	Tertiary halo	32
Diffraction spike	4	Bad pixel	64
Primary halo	8	Manually masked	128

Table 5. Percentage of masked area.

Filter	Not masked	Automatically masked	Manually masked
<i>u</i>	97	1	2
<i>g</i>	86	7	7
<i>r</i>	78	12	10
<i>i</i>	77	9	14

significantly smaller percentage of masked pixels. The high fraction of area that is manually masked in *i*-band is due to the higher frequency and severity of scattered light issues (see Sect. 5.5) caused by moonlight and higher sky brightness. Taking into account the nominal area covered by KiDS-ESO-DR1/2 the total unmasked area is approximately 120 square degrees.

4.5. Source extraction and star/galaxy separation

Single-band source lists were included in KiDS-ESO-DR1, while KiDS-ESO-DR2 contains both single-band source lists, as well as a multi-band source catalogue encompassing the combined area. The single-band source lists are provided per survey tile, while the catalogue, although split into files corresponding to single tiles, is constructed as a single catalogue. Both the source lists and the catalogue are intended as “general purpose” catalogues.

4.5.1. Single-band source lists

Source list extraction and star/galaxy (hereafter S/G) separation is achieved with an automated stand-alone procedure optimized for KiDS data: KiDS-CAT. This procedure, the backbone of which is formed by SExtractor, performs the following steps separately for each filter.

1. SExtractor is run on the stacked image to measure the full width at half maximum (FWHM) of all sources. High-confidence star candidates are then identified based on a number of criteria including signal-to-noise ratio (S/N) and ellipticity cuts (for details see La Barbera et al. 2008).
2. The average PSF FWHM is calculated by applying the bi-weight location estimator to the FWHM distribution of the high-confidence star candidates.
3. A second pass of SExtractor is run with SEEING_FWHM set to the derived average PSF FWHM. During this second pass the image is background-subtracted, filtered and thresholded “on the fly”. Detected sources are then de-blended, cleaned, photometered, and classified. A number of SExtractor input parameters are set individually for each image (e.g., SEEING_FWHM and GAIN), while others have been optimized to provide the best compromise between completeness and spurious detections (see Data Quality section below). The detection set-up used is summarized in Table 6; a full SExtractor configuration

file is available online¹⁰. Apart from isophotal magnitudes and Kron-like elliptical aperture magnitudes, a large number of aperture fluxes are included in the source lists. This allows users to estimate aperture corrections and total source magnitudes. All parameters provided in the source lists are listed in the Data Format section below.

4. S/G separation is performed based on the CLASS_STAR (star classification) and S/N parameters provided by SExtractor and consists of the following steps:
 - In the S/N range where the high-confidence star candidates are located (the red dots in Fig. 8) the bi-weight estimator is used to define their CLASS_STAR location, θ , and its width, σ ; a lower envelope of $\theta - 4\sigma$ is defined.
 - At S/N below that of the high-confidence star candidates, a running median CLASS_STAR value is computed based on all sources with CLASS_STAR > 0.8. This running median is shifted downwards to match the $\theta - 4\sigma$ locus. The resulting curve (blue curve in Fig. 8) defines the separation of stars and galaxies.

The source magnitudes and fluxes in the final source lists are for zero airmass, but not corrected for Galactic foreground or intergalactic extinction. The result of the S/G classification is available in the source lists via the 2DPHOT flag. Flag values are: 1 (high-confidence star candidates), 2 (objects with FWHM smaller than stars in the stellar locus, e.g., some cosmic-rays and/or other unreliable sources), 4 (stars according to S/G separation), and 0 otherwise (galaxies); flag values are summed, so 2DPHOT = 5 signifies a high-confidence star candidate that is also above the S/G separation line. Table A.1 lists all columns present in these source lists.

4.5.2. Multi-band catalogue

The multi-band catalogue delivered as part of KiDS-ESO-DR2 is intended as a “general purpose” catalogue and relies on the double-image mode of SExtractor and also incorporates information obtained using the KiDS-CAT software described above. SExtractor is run four times for each tile, using the *u*, *g*, *r* and *i* KiDS-ESO-DR1/2 coadds as measurement images, to extract source fluxes in each of the filters. The *r*-band coadd is used as detection image in all runs, since it provides the highest image-quality in almost all cases. For the same reason, several shape measurements are based only on the *r*-band data. In the future, it is foreseen that the catalogue S/G separation will make use of colour information and/or PSF modeling. Currently the S/G separation information included in the catalogue is the same as in the *r*-band source list. The detection set-up is identical to that employed for the source detection for the single-band source list (Table 6). Masking information is provided for all filters in the same fashion as in the single-band source lists. Compared to the single-band source lists the number of measured parameters is reduced. Table B.1 lists the columns present in these source lists.

To account for seeing differences between filters aperture corrected fluxes are provided in the catalogue. The aperture corrections were calculated for each filter by comparing the aperture fluxes with the flux in a 30 pixel aperture, the aperture used for photometric calibration, and the aperture-corrected fluxes are included in the catalogue as separate columns. Source magnitudes and fluxes are not corrected for Galactic foreground or intergalactic extinction.

¹⁰ http://kids.strw.leidenuniv.nl/DR1/example_config_sex

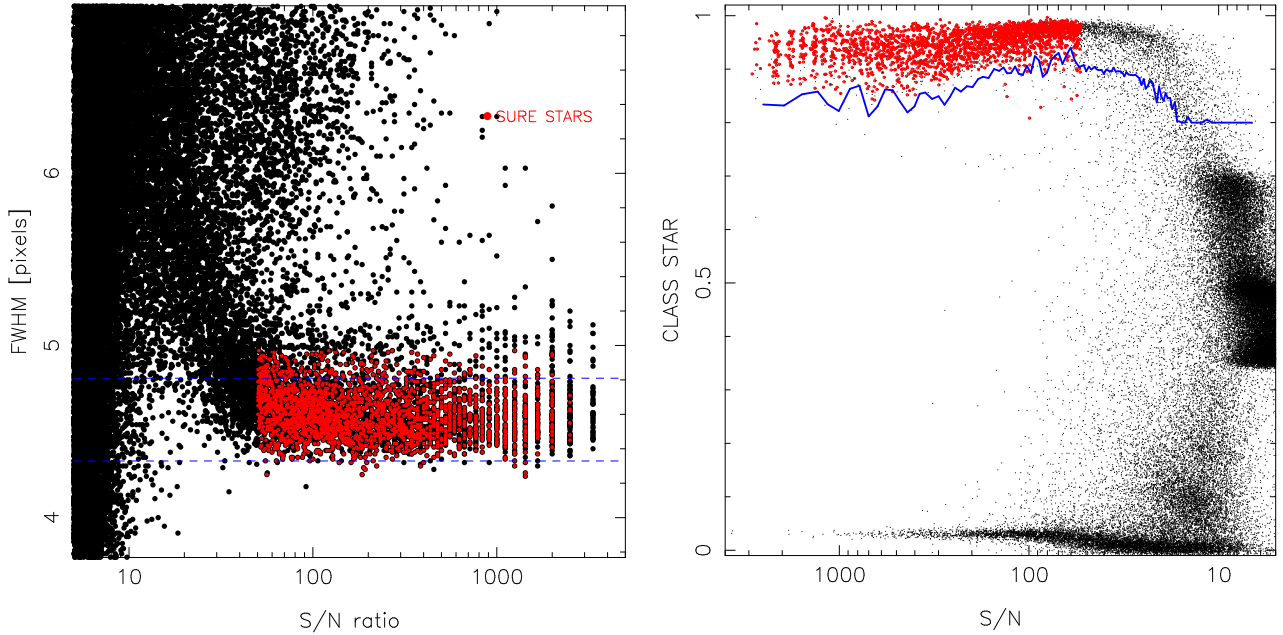

Fig. 8. High-confidence star candidates and star/galaxy separation. *Left:* the high-confidence star candidates (red dots) are used to locate the stellar locus and calculate the average FWHM of the image. *Right:* example of star/galaxy separation; at $S/N > 50$, the high-confidence star candidates (red dots) are used to define the blue line; at lower S/N , all sources with $CLASS_STAR > 0.8$ are used; sources above the blue line are classified as stars.

Table 6. Detection set-up for KiDS-ESO-DR1 and KiDS-ESO-DR2 single-band source lists.

Parameter	Value	Description
DETECT_THRESH	1.5	$\langle \text{sigmas} \rangle$ or $\langle \text{threshold} \rangle, \langle ZP \rangle$ in $\text{mag}/\text{arcsec}^2$
DETECT_MINAREA	3	minimum number of pixels above threshold
ANALYSIS_THRESH	1.5	$\langle \text{sigmas} \rangle$ or $\langle \text{threshold} \rangle, \langle ZP \rangle$ in $\text{mag}/\text{arcsec}^2$
DEBLEND_NTHRESH	32	Number of deblending sub-thresholds
DEBLEND_MINCONT	0.001	Minimum contrast parameter for deblending
FILTER	Y	Apply filter for detection (Y or N)
FILTER_NAME	default.conv	Name of the file containing the filter
CLEAN	Y	Clean spurious detections? (Y or N)
CLEAN_PARAM	1.0	Cleaning efficiency
BACK_SIZE	256	Background mesh: $\langle \text{size} \rangle$ or $\langle \text{width} \rangle, \langle \text{height} \rangle$
BACK_FILTERSIZE	3	Background filter: $\langle \text{size} \rangle$ or $\langle \text{width} \rangle, \langle \text{height} \rangle$
BACKPHOTO_TYPE	LOCAL	can be GLOBAL or LOCAL
BACKPHOTO_THICK	24	thickness of the background LOCAL annulus

In order to prevent sources in tile overlaps to appear as multiple entries in the catalogue, the survey tiles have been cropped and connect seamlessly to one another. This results in slightly shallower data along the edges of the tiles (Fig. 3), similar to the areas partially covered by CCD gaps. Overall, all included areas are covered by at least three exposures. In future releases this will be improved by combining information from multiple tiles in overlap regions.

5. Data quality

5.1. Intrinsic data quality

In Fig. 9 the obtained seeing (FWHM), PSF ellipticity, and limiting magnitude distributions per filter are shown, to illustrate the raw data quality. The PSF ellipticity is defined here as $1 - B/A$, where A and B are the semi-major and semi-minor axis, respectively. Limiting magnitudes are 5σ AB in a $2''$ aperture and determined by a fit to the median S/N , estimated by

$1/\text{MAGERR_AUTO}$, as function of magnitude. In case of the filters observed in dark time (u, g, r) the FWHM distributions reflect the different observing constraints, with r -band taking the best conditions. Since i -band is the only filter in which the data are obtained in bright time, it is observed under a large range of seeing conditions. Average PSF ellipticities are always small: <0.1 (the average is over the absolute value of ellipticity, regardless of the direction of ellipticity). The wide range of limiting magnitudes in i -band is caused by the large range in moon phase and thus sky brightness.

5.1.1. Point-spread-function

Designed with optimal image quality over the full square degree field-of-view in mind, the VST/OmegaCAM system is capable of delivering images with an extremely uniform PSF. A typical example of the PSF ellipticity and size pattern for an observation taken with a nominal system set-up is shown in the left panel of Fig. 10. Of course, as must be expected from a newly

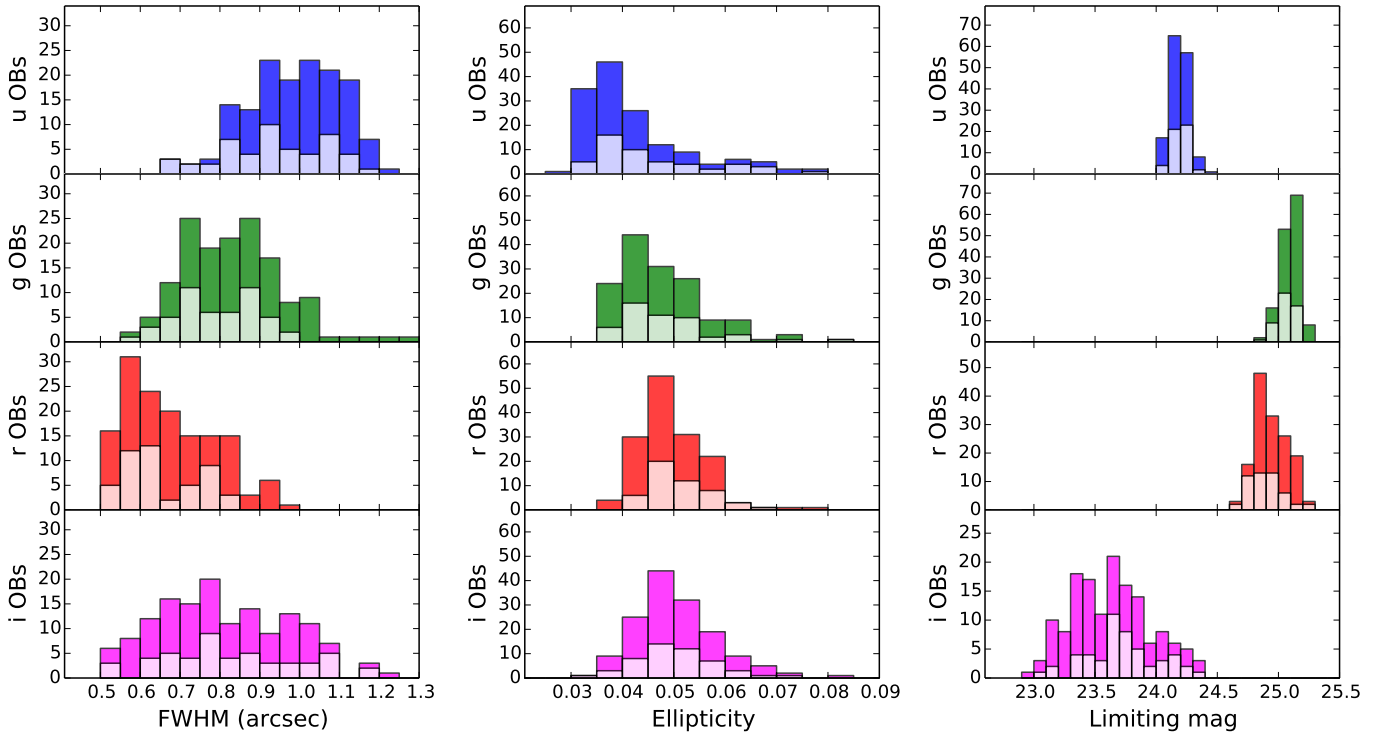

Fig. 9. Data quality for KiDS-ESO-DR1 and KiDS-ESO-DR2. *Left:* average PSF size (FWHM) distributions; *center:* average PSF ellipticity distributions; *right:* limiting magnitude distributions (5σ AB in $2''$ aperture). The distributions are per filter: *from top to bottom* *u*, *g*, *r*, and *i*, respectively. The lighter portions of the histograms correspond to the 50 tiles in KiDS-ESO-DR1 and the darker portions to the 98 tiles in KiDS-ESO-DR2.

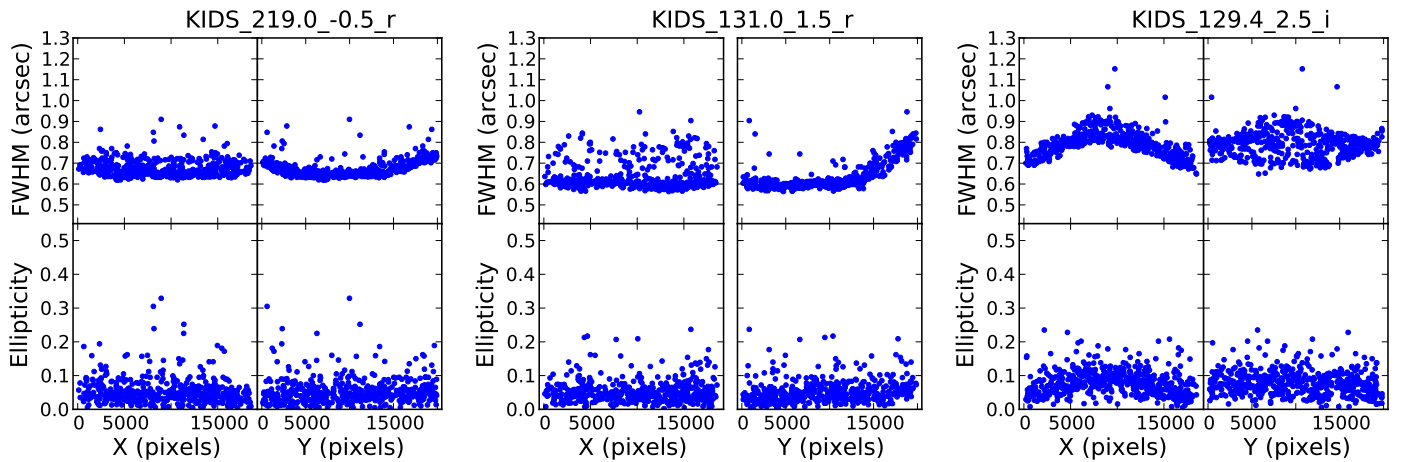

Fig. 10. Examples of significant PSF size and ellipticity variation across three KiDS image stacks: KIDS_219.0_-0.5_r (*left*), KIDS_131.0_1.5_r (*center*), and KIDS_129.4_2.5_i (*right*). In each subplot the upper panels show the FWHM in arcseconds and the lower panels the ellipticity, both plotted versus pixel coordinates *X* (*left panels*) and *Y* (*right panels*). Points correspond to the 500 brightest, unsaturated and unflagged point sources in each field.

commissioned instrument, the set-up of the optical system is not always perfect and different imperfections can lead to a variety of deviations from a stable and round PSF. Most commonly encountered patterns are related to imperfect focus (increased PSF size either on the outside or on the inside of the FOV) and mis-alignment of the secondary mirror (increased PSF size and ellipticity along one edge of the FOV).

To quantify the stability of the PSF we calculate a PSF size and ellipticity for every observation based on the PSF sizes in 32 regions in the coadded image that correspond roughly to the 32 CCDs. Systematic variations in ellipticity are usually less

clear than in PSF size (see Fig. 10), which is why the latter is used for monitoring PSF stability. The average PSF size in the 4 regions with the smallest PSF is subtracted from the average PSF size in the 4 regions with the largest PSF, and the result divided by the average PSF size of the whole image. The distribution per filter of this PSF size nonuniformity is shown versus the median FWHM in Fig. 11. As the median PSF size (i.e. the seeing) increases, the nonuniformity drops, as any differences due to optical imperfections are smoothed out. However, even during very good seeing conditions the PSF size variation rarely exceeds 25% and in most cases is around 10%.

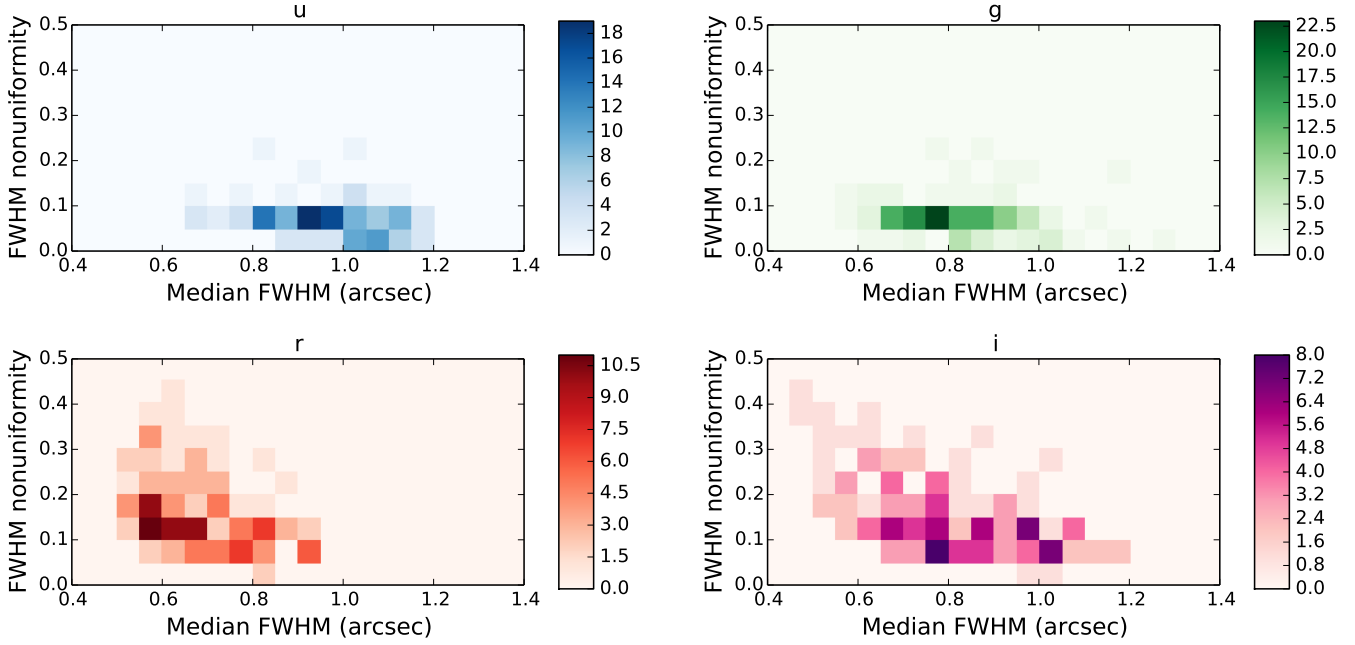

Fig. 11. PSF size nonuniformity vs. median PSF size for KiDS-ESO-DR1/2 tiles, per filter (*top left: u; top right: g; bottom left: r; bottom right: i*). The nonuniformity is calculated as the PSF size (FWHM) difference between the 4 CCDs with the biggest PSF and the 4 CCDs with the smallest PSF within a coadd, divided by the average PSF size. The colour scale indicates the number of tiles in each bin.

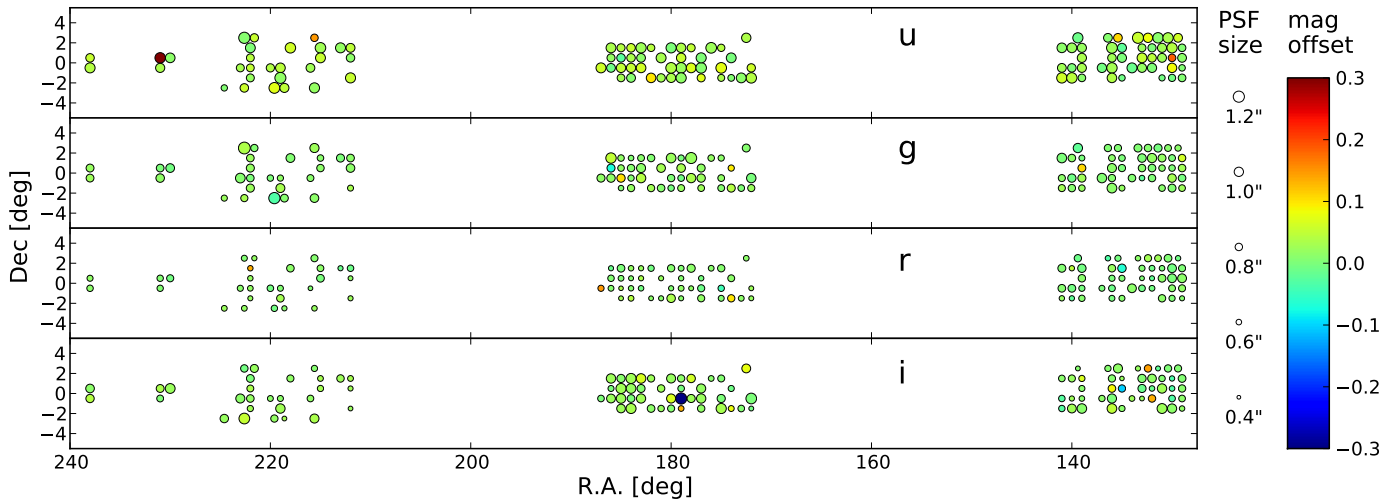

Fig. 12. PSF sizes and photometric calibration for all tiles in KiDS-North as function of right ascension and declination. The average PSF size in each coadded image is indicated by the size of the circle, and the magnitude offset with respect to SDSS by its color. From top to bottom the panels correspond to the *u*, *g*, *r*, and *i* filters.

The median PSF sizes for all tiles in the KiDS-North field are indicated in Fig. 12. Both in KiDS-North and KiDS-South there are no systematic gradients in PSF size over the survey area.

5.2. Photometric quality

The matter of photometric quality can be divided in two parts, namely the uniformity of the photometry within each tile, and the quality of the photometric calibration per tile/filter. Since the distribution of tiles included in KiDS-ESO-DR1/2 is not contiguous, with many isolated tiles, a complete photometric homogenization of the entire data set is impossible, and the photometric calibration is currently done per tile and per filter. The quality of the photometry will improve greatly in future releases

when, using significant contiguous areas, a global calibration for the entire survey will be performed.

5.2.1. Comparison to SDSS

Both the internal photometric homogeneity within a coadd and the quality of the absolute photometric scale is assessed by comparing the KiDS photometry to SDSS DR8 (Aihara et al. 2011), which is photometrically stable to $\sim 1\%$ (Padmanabhan et al. 2008). For this purpose, the aperture-corrected magnitudes in the multi-band catalogue were compared to PSF magnitudes of stars in SDSS DR8. Only unmasked stars with photometric uncertainties in both KiDS and SDSS smaller than 0.02 mag in *g*, *r*, and *i* or 0.03 mag in *u* were used. This comparison is only possible

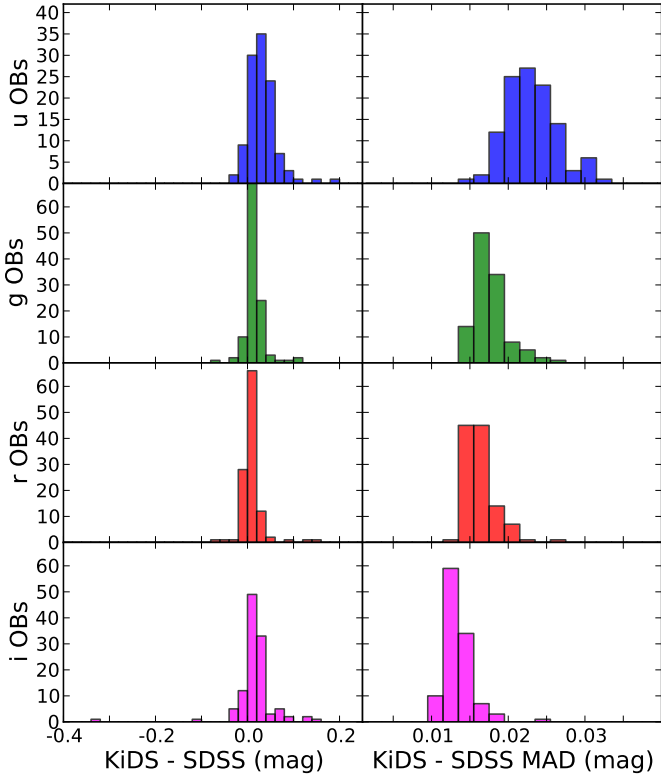

Fig. 13. Comparison of KiDS aperture-corrected photometry to SDSS DR8 PSF photometry for stars in KiDS-North. Distributions of the median offsets are shown in the left column and the distributions of Median Absolute Deviations from these offsets in the right column. In both columns the subpanels correspond, from top to bottom, to u , g , r and i .

for all tiles in the KiDS-North field, but since KiDS-South was calibrated in the same way as KiDS-North, we expect the conclusions to hold for all data.

The consistency of the photometric calibration is illustrated in Fig. 13, where histograms of the distributions of photometric offsets between KiDS and SDSS are shown for the overlapping tiles in KiDS-North. A systematic offset of ~ 0.02 mag is present in all filters, possibly due to the fact that nightly zero-points are determined using a fixed aperture on stars in the SA field without aperture correction. The scatter and occasional outliers are due to non-photometric conditions (during either KiDS or SA field observations) and, particularly in case of the u -band, use of default zero-points. In Fig. 12 the photometric offsets are plotted as function of RA and Dec, demonstrating that there are no large-scale gradients present. All photometric offsets determined from this comparison with SDSS are available in the Source catalogue table on the KiDS website¹¹.

Figure 14 shows the residuals between KiDS and SDSS DR8 magnitudes for one tile (KIDS_129.0_-0.5), which is a representative example. Generally speaking, the photometry in a filter within one tile is uniform to a few percent. The right column of the left panel in Fig. 13 shows the distribution of the Median Absolute Deviation (MAD) of the stellar photometry between KiDS and SDSS for the tiles in KiDS-North, demonstrating the photometric stability within survey tiles. The relatively poor photometry in u -band is due to the lack of photometric homogenization within a tile.

¹¹ <http://kids.strw.leidenuniv.nl/DR2>

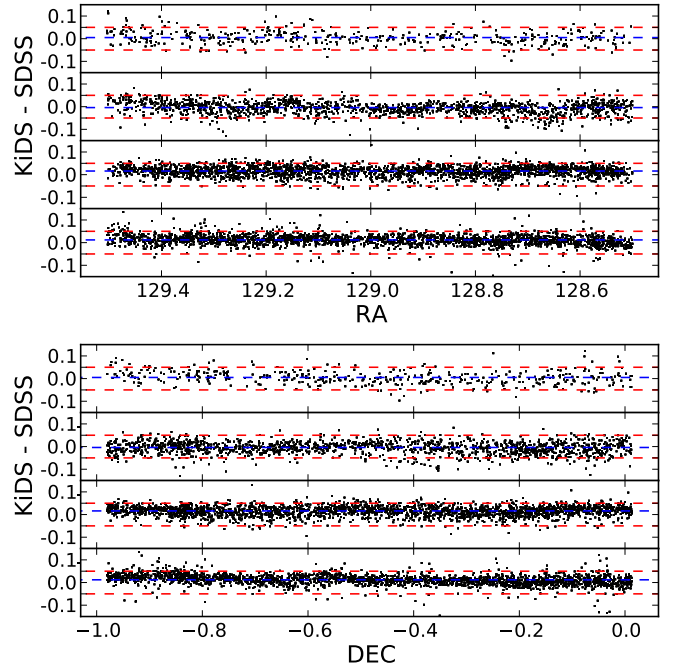

Fig. 14. Photometric comparison between aperture-corrected KiDS photometry and SDSS DR8 PSF photometry for (unmasked) stars in tile KIDS_129.0_-0.5. *Top*: offsets versus right ascension. *Bottom*: offsets versus declination. Subpanels correspond, from top to bottom, to u , g , r and i , respectively. Each dot corresponds to a star, with the average indicated by a blue dashed line and with red dotted lines indicating $+0.05$ and -0.05 mag.

5.2.2. Stellar locus

A second quality assessment of the photometry is done by comparing stellar photometry to empirical stellar loci, in the form of the “principal colours” as defined by Ivezić et al. (2004) based on SDSS photometry. Only unmasked and unflagged stars with $r < 21$ are used for this analysis. Although small colour terms exist between KiDS and SDSS the stellar loci based on SDSS are a powerful tool to verify the photometric stability over the currently released tiles. Once more complete sky coverage allows an overall photometric calibration of the KiDS data, accurate stellar loci in the KiDS filters will be derived.

Figure 15 shows the stellar locus for the tile KIDS_129.0_-0.5 in the three principal colour planes. These colour planes are different combinations of the $ugri$ filters and denoted by s , w and x . The median $p2$ colours are calculated for each of $p2s$, $p2w$ and $p2x$ by choosing all stars within the indicated limits and after clipping all stars more than 200 mmag away from the initial median $p2$ colour. In Fig. 16 the distributions of the median principal colours are shown, together with the typical width of the stellar locus, measured by the standard deviation. The narrow distributions indicate that the colour of the stellar locus is typically stable to within 20 mmag. Also the stellar locus width is always stable to within 10 mmag. The large width of the stellar locus in $p2x$ is caused by the fact that this part of the locus is made up of relatively faint stars with large photometric uncertainties.

In this analysis three tiles stand out that have a median $p2w$ colour of >100 mmag. Comparing these with the SDSS photometry as discussed above shows that one corresponds to the tile with the largest offset (-0.32 mag) in i and two correspond to tiles with large offsets (>0.1 mag) in r .

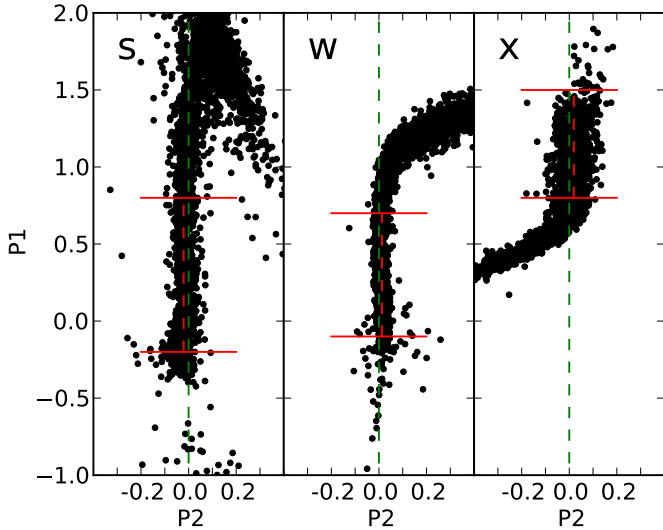

Fig. 15. Stellar locus in “principal colour” space for tile KIDS_129.0_-0.5. For the definition of the three colour planes see Ivezić et al. (2004). In SDSS filters the stellar locus should lie at $p2s = p2w = p2x = 0$, indicated by the green dashed line. The dashed red line shows the median stellar locus colour and the solid red lines the range in the $p1$ colours used for this analysis. Only unflagged stars with $r < 21$ are plotted here.

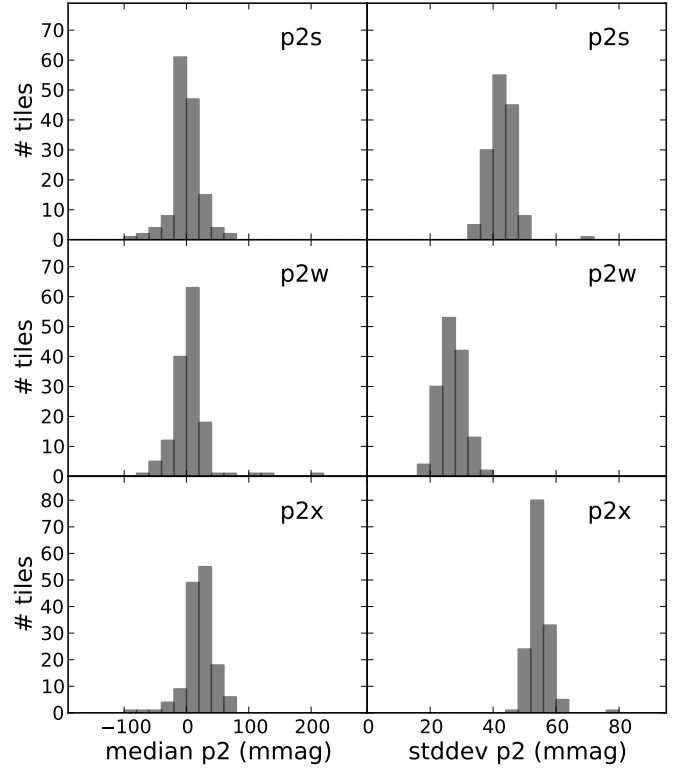

Fig. 16. Stellar locus colour analysis using “principal colours” defined in Ivezić et al. (2004) and based on KiDS aperture-corrected stellar photometry for all tiles. Distributions of the offsets from the expected stellar locus colour are plotted in the *left column*. In the *right column* the distributions of the widths of the stellar locus (measured by standard deviation) are shown.

5.2.3. Tile overlaps

Finally, we analyze the tile-to-tile photometric offsets directly from the KiDS data, using the overlapping areas between the tiles where available. This is done per filter, and only stars with a magnitude brighter than 22 in the respective filter are matched. In u this results in a total number of sources per overlap region varying between 20 and 300, in g and r between 50 and 600 and in i between 100 and 1000. In some cases the PSF deteriorates at the edge of a tile, as described Sect. 5.1.1, and the aperture-corrected magnitudes may be affected. For this reason MAG_ISO magnitudes are used for this overlap analysis. The distributions of magnitude offsets in each filter, as determined from the tile overlaps, are shown in Fig. 17. In the gri filters the offsets are typically 0.02 mag, and for u this increases to typically 0.04 mag. Taking into account that the photometry in the tile edges is of slightly poorer quality than in the center, due to the fact that these data are less deep, these values are in good agreement with the photometric comparison to SDSS.

5.3. Astrometric quality

The accuracy of the absolute astrometry (“KiDS vs. 2MASS”) is uniform over a coadd, with typical 2-dimensional (2D) rms of $0.31''$ in g , r , and i , and $0.25''$ in u , in line with expectations based on the fact that the majority of reference stars used is relatively faint. The lower rms in u -band is most likely due to the fact that in this band on average brighter 2MASS sources are selected as reference sources. The accuracy of the relative astrometry (“KiDS vs. KiDS”), measured by the 2D positional residuals of sources between dithers, is also uniform across a single coadd. In Fig. 18 the accuracy of this relative astrometry of all coadds is shown. The typical 2D rms is $\sim 0.03''$ in all filters, but with a larger scatter in u due to the smaller number of available reference sources.

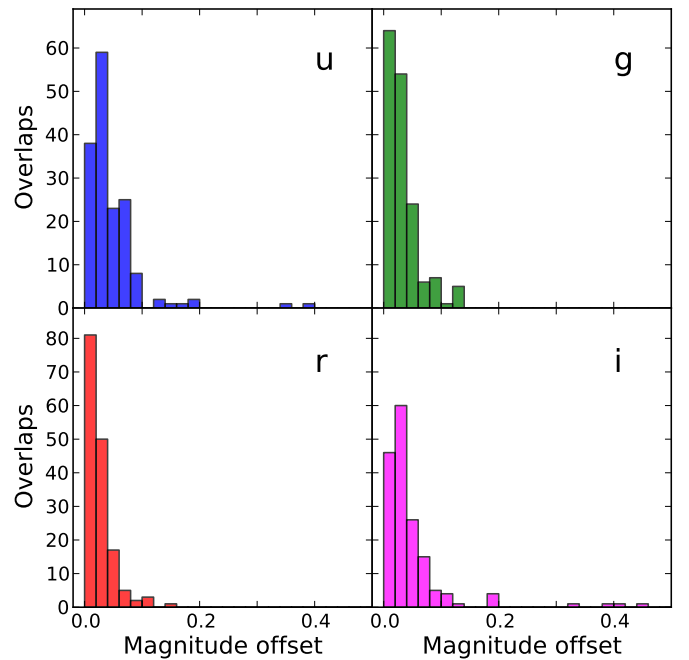

Fig. 17. Tile-to-tile magnitude offsets in each filter measured from the overlap regions. In each available overlap region unflagged stars were selected brighter than 22 mag in the filter considered, and their MAG_ISO magnitudes were compared, yielding a positive, mean offset.

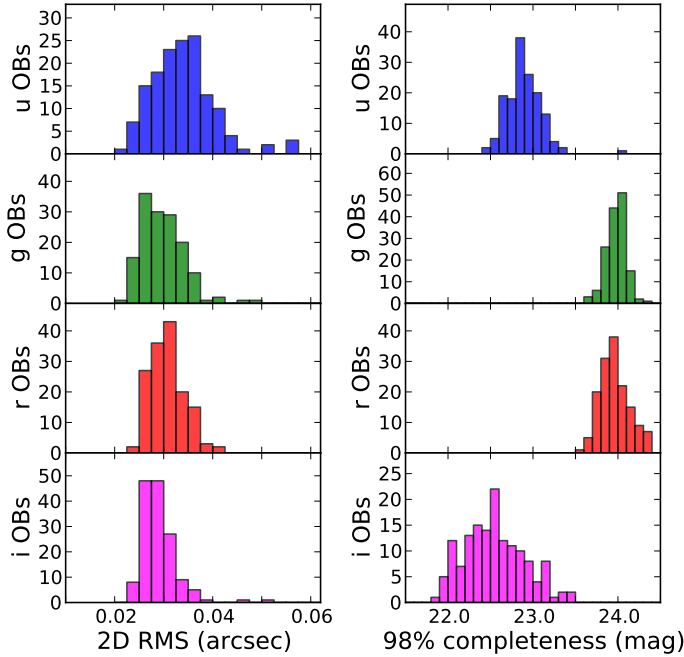

Fig. 18. Overview of the astrometric quality and completeness of KiDS-ESO-DR1 and KiDS-ESO-DR2 (all data contained in the multi-band catalogue). *Left:* histogram of the median relative astrometric offsets between the individual dithers and the corresponding coadd per survey tile. *Right:* 98% completeness magnitude distributions for all tiles, based on the method of Garilli et al. (1999). In both columns the panels correspond to u , g , r , and i from top to bottom.

5.4. Completeness and contamination

Contamination of the multi-band catalogue by spurious sources was analyzed by means of a comparison of the overlap between KiDS and the CFHT Legacy Survey¹², the main deeper survey overlapping with the current data releases (CFHTLS-W2, using their final data release T0007¹³). For the analysis it is assumed that all KiDS sources not detected in CFHTLS-W2 are spurious. Since some fraction of real sources might be absent in the CFHTLS catalogues, the spurious fractions derived should be considered upper limits.

Figure 19 shows the spurious fractions derived from this comparison as function of magnitude (r -band MAG_ISO) and signal-to-noise (in a $2''$ aperture). When all sources in the catalogue are considered the fraction of spurious sources is estimated to be $<5\%$ down to a very low S/N of ~ 5 within a $2''$ aperture. Filtering sources based on masking information reduces this fraction to $\sim 2\%$, demonstrating that caution is required when using faint sources in masked regions. When sources are filtered both on masking information as well as SEXTRACTOR detection flags, the spurious fractions drops even further to $\sim 1\%$, yielding a very clean catalogue down to the detection limit.

An internal estimate of the completeness for the KiDS data is provided per tile, based on the method of Garilli et al. (1999). It determines the magnitude at which objects start to be lost in the source list because they are below the brightness threshold in the detection cell. The implementation is similar to La Barbera et al. (2010). Estimates of the completeness obtained by comparison to deeper CFHTLS-W2 data are consistent with these internally derived values. The distributions of the 98% completeness

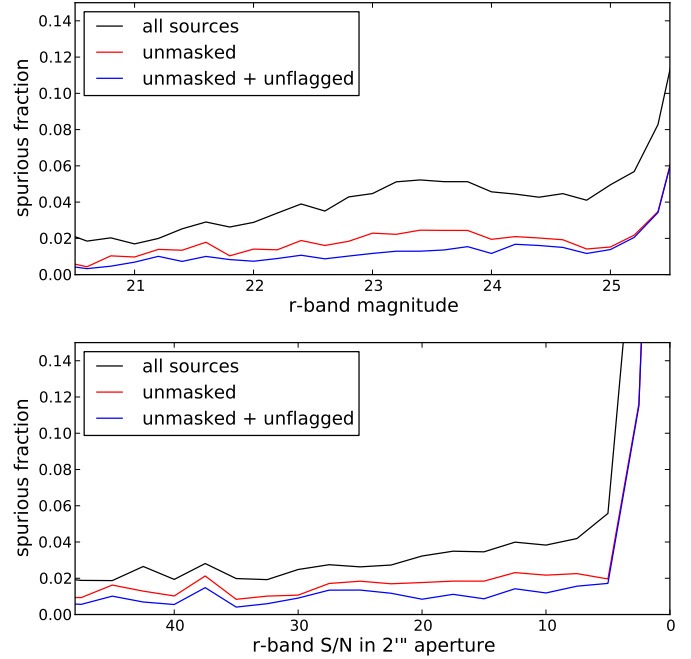

Fig. 19. Spurious source contamination in the overlap between the KiDS multi-band catalogue and the CFHTLS-W2 field (this corresponds to the KiDS tiles KiDS_135.0_-1.5 and KiDS_136.0_-1.5). *Top:* spurious fraction vs. r -band magnitude (MAG_AUTO). *Bottom:* spurious fraction vs. signal-to-noise in a $2''$ aperture. The black line corresponds to all sources, while the red line excludes sources in masked areas, and the blue line excludes sources in masked areas and sources with a non-zero SEXTRACTOR flag.

magnitudes for all tiles are shown in Fig. 18. Comparison with Fig. 9 shows that the 98% completeness limits are typically ~ 1 mag brighter than the limiting magnitude for g , r and i and ~ 1.3 mag brighter in u . For the completeness of the multi-band catalogue the values for the r -band of each tile apply.

5.5. Data foibles

5.5.1. Scattered light and reflections

Some of the main challenges in the analysis of early VST/OmegaCAM data are related to scattered light and reflections. Due to the open structure of the telescope, light from sources outside the field-of-view often affects the observations. This expresses itself in a number of ways:

- Reflections: in some cases strong reflected light patterns are seen in the focal plane; these are caused by light from bright point sources outside the field-of-view and can occur in all filters. Some examples are shown in Fig. 20a.
- Vignetting by CCD masks: vignetting and scattering by the masks present at the corners of the focal plane array, and at the gaps between the rows of CCDs; this effect is particularly strong in i -band due to the bright observing conditions. The effect near the CCD gaps is largely corrected for, but in many cases the areas in the corners of the CCD array is strongly affected. Examples are shown in Fig. 20b.
- Extended background artifacts: related to the reflections mentioned before, this is mostly seen in i -band and probably caused by moonlight. An example is shown in Fig. 20c. Most of these effects are not (yet) corrected for in the current data processing, but strongly affected regions are included

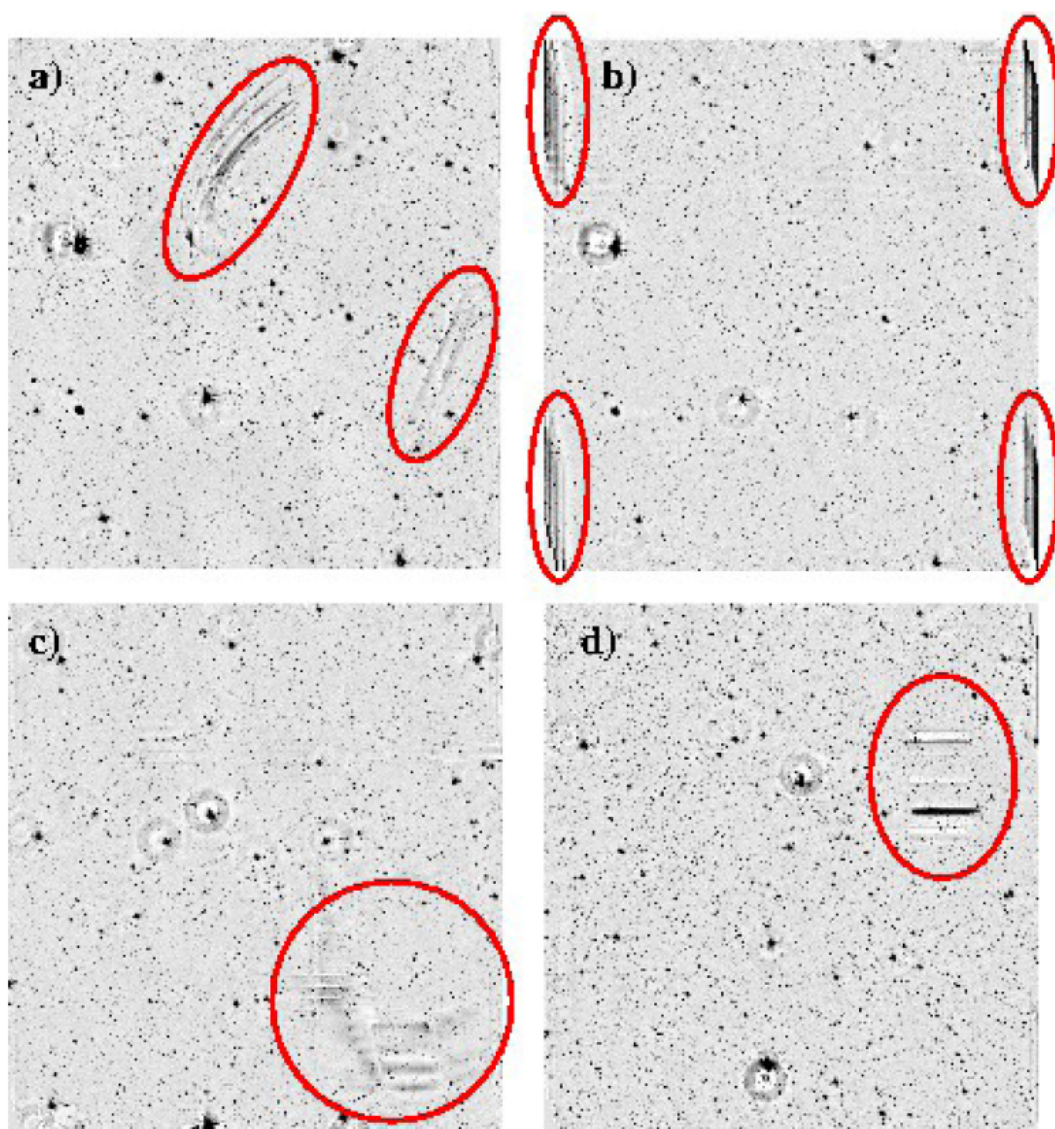

Fig. 20. Examples of known issues in the KiDS-ESO-DR1/2 VST/OmegaCAM data, highlighted by the red ellipses. **a)** Light patterns caused by reflections and scattered light of bright sources outside the FOV. **b)** Vignetting and scattering by CCD masks at the corners of the CCD array. **c)** Extended background structures caused by scattering of moonlight. **d)** Patterns caused by defective video board of CCD 82. Improved telescope baffles installed in early 2014 significantly reduce the occurrence of scattered light in future data releases.

in the image masks and affected sources are flagged in the source lists and catalogue.

Improvements to the telescope baffles that were installed in early 2014 significantly improve scattered light suppression.

5.5.2. Individual CCD issues

There are two issues related to individual CCDs that noticeably affect this data delivery:

- CCD 82: this CCD suffered from random gain jumps and related artifacts until its video board was replaced on June 2 2012. Artefacts as shown in Fig. 20d are sometimes visible in the image stacks due to this problem. Photometry in this CCD can be used due to the cross-calibration with neighbouring CCDs in the dithered exposures, but part of the CCD is lost. These features are included in the image masks and affected sources are flagged.
- CCD 93: during a few nights in September 2011 (Early Science Time) one CCD was effectively dead due to a video

cable problem. One observation included in this data delivery does not include this CCD: the *i*-band observation of KIDS_341.2_-32.1.

6. First scientific applications

The Kilo-Degree Survey was designed for the central science case of mapping the large-scale matter distribution in the Universe through weak gravitational lensing and photometric redshifts. Several other science cases were also identified from the early design stages including studying the structure of galaxy halos, the evolution of galaxies and galaxy clusters, the stellar halo of the Milky Way, and searching for rare objects such as high-redshift QSOs and strong gravitational lenses. While for the main science goal of KiDS the full survey area is required, scientific analyses focusing on the other science cases are currently already on-going. Below we demonstrate the quality and promise of KiDS by means of these on-going research efforts.

6.1. Photometric redshifts and weak gravitational lensing

An analysis of the weak gravitational lensing masses of galaxies and groups in the KiDS images is one of the main early scientific goals of the survey (Viola et al. 2015; van Uitert et al. 2015; Sifón et al. 2015). Such an analysis requires two types of measurements from the KiDS data: galaxy shapes for shear measurements, and galaxy colours for photometric redshifts. The shapes are measured with a dedicated pipeline based on the CFHTLenS analysis (Heymans et al. 2012; Erben et al. 2013; Miller et al. 2013) that combines information from individual exposures and avoids regridding of the pixels to maintain image fidelity as much as possible. The colours and photometric redshifts are derived from the BPZ code (Benítez 2000; Coe et al. 2006) applied to the output from a PSF-homogenized photometry pipeline – again an evolution from the CFHTLenS analysis pipeline, see Hildebrandt et al. (2012) – which runs on the calibrated stacked images released in KiDS-ESO-DR1/2. Further details of these dedicated analyses are presented in Kuijken et al. (2015).

As an illustration of the quality of the photometric redshifts, in Fig. 21 we show the angular cross-correlations $w(\theta)$ of the positions of galaxies in different photometric redshift bins, on scales between 1 and 30 arcmin (Erben et al. 2009; Benjamin et al. 2010). We use ATHENA (Kilbinger et al. 2014) to calculate $w(\theta)$ using the Landy & Szalay (1993) estimator. Errors are obtained from jackknife resampling, with each pointing being a jackknife sub-sample. The figure shows a clear clustering signal of galaxies within the same redshift bin (panels on the diagonal). Most off-diagonal panels show a smaller cross-correlation amplitude than the corresponding auto-correlations, and mostly this signal is seen only between neighbouring redshift bins, as would be caused by scatter of the photometric redshift estimates into neighbouring bins. The fact that no strong signal is seen further away from the diagonal shows that the level of catastrophic failures in the redshifts is low, and provides confidence in the photometric redshifts as well as the underlying photometry reported here.

This photometric redshift-only cross-correlation check is complementary to the spectroscopic redshift-photometric redshift cross-correlations presented in Kuijken et al. (2015). The latter analysis has the advantage of utilising spectroscopic redshifts, which provide a better representation of the “absolute truth”; however, the spectroscopic redshifts only reach up to $z \sim 0.5$, so there is additional information provided by the photometric redshift-only cross-correlations out to $z \sim 1$. We refer the interested reader to Kuijken et al. (2015) for details of the cross-correlation analysis between the photometric redshifts and the available spectroscopic redshifts.

6.2. Photometric redshifts from machine learning

Apart from the photometric redshifts described in Sect. 6.1, photometric redshifts are also derived from KiDS-ESO-DR1/2 *ugri* photometry using the supervised machine learning model MLPQNA: a Multi-Layer Perceptron feed-forward neural network providing a general framework for representing nonlinear functional mappings between input and output variables. QNA stands for Quasi Newton Algorithm, a variable metric method used to solve optimization problems (Davidon 1991) that, when implemented as the learning rule of a MLP, can be used to find the stationary (i.e. the zero gradient) point of the learning function. The QNA implemented here is the L-BFGS algorithm from Shanno (1970). Supervised methods use an extensive set (the knowledge base or KB) of objects for which the output (in this

case the redshift) is known a-priori to learn the mapping function that transforms the input data (in this case the photometric quantities) into the desired output. Usually the KB is split into three different subsets: a *training set* for training the method, a *validation set* for validating the training in particular against overfitting, and a *test set* for evaluating the overall performance of the model (Cavuoti et al. 2012; Brescia et al. 2013). In the method used here the validation is embedded into the training phase, by means of the standard leave-one-out k-fold cross validation mechanism (Geisser 1975). Performances are always derived blindly, i.e. using a test set formed by objects which have never been fed to the network during either training or validation. The MLPQNA method has been successfully used in many experiments on different data sets, often composed through accurate cross-matching among public surveys (SDSS for galaxies: Brescia et al. 2014; UKIDSS, SDSS, GALEX and WISE for quasars: Brescia et al. 2013; CLASH-VLT data for galaxies: Biviano et al. 2013).

The KB of spectroscopic redshifts was obtained by merging the spectroscopic datasets from GAMA data release 2 (Liske et al. 2015) and SDSS-III data release 9 (Ahn et al. 2012), while for the KiDS photometry two different aperture magnitudes were adopted. The final KB includes the optical magnitudes (*ugri*) within 4'' and 6'' diameters and SDSS and GAMA heliocentric spectroscopic redshifts. GAMA redshifts come with the normalized quality flag NQ.

A training set and a test set were created by splitting the KB into two parts of 60% and 40%, respectively. With these data sets two experiments were performed, one using only the GAMA high-quality (HQ, $NQ > 2$) spectroscopic redshifts and one using a mix of GAMA and SDSS spectroscopic information. These experiments are illustrated in Fig. 22. To quantify the quality of the results we use the standard normalized photometric redshift error Δz_{norm} defined as $|z_{\text{spec}} - z_{\text{phot}}| / (z_{\text{spec}} + 1)$. We find a 1σ scatter in Δz_{norm} of 0.027 and 0.031 and a fraction of catastrophic outliers ($|\Delta z_{\text{norm}}| > 0.15$) of 0.25% and 0.39% for the high-quality GAMA and the GAMA+SDSS spectroscopic data sets, respectively. The mixture of GAMA HQ + SDSS spectroscopic data slightly extends the KB to higher redshifts, but since there is still very limited information at $z_{\text{spec}} > 0.45$, this does not significantly increase the performance at higher redshift. Finally, the presence of objects at the minimum $z_{\text{spec}} = 0$ indicates a residual presence of stars within the sample. Further information about the experiments, results and the produced catalogue of photometric redshifts is reported in Cavuoti et al. (2015). A detailed comparison with redshifts from SED-fitting will be presented in a forthcoming paper (Cavuoti et al., in prep.).

6.3. Galaxy structural parameters and scaling relations

Galaxies are the building blocks of the Universe and within the framework of hierarchical structure formation they form bottom-up, with smaller objects forming first, then merging into massive structures (e.g. De Lucia et al. 2006; Trujillo et al. 2006). However, high-mass galaxies seem to have formed most of their stars in earlier epochs and over a shorter time interval than the lower mass ones (“downsizing” scenario, Fontanot et al. 2009). Characterising the properties of the luminous matter and the way this has been assembled into dark-matter haloes is crucial to reconcile theory and observations. Making use of the high spatial resolution, depth and area coverage of KiDS we aim to measure, across different redshift slices:

- total luminosity and the stellar mass through SED fitting (e.g. Le PHARE, Arnouts et al. 1999);

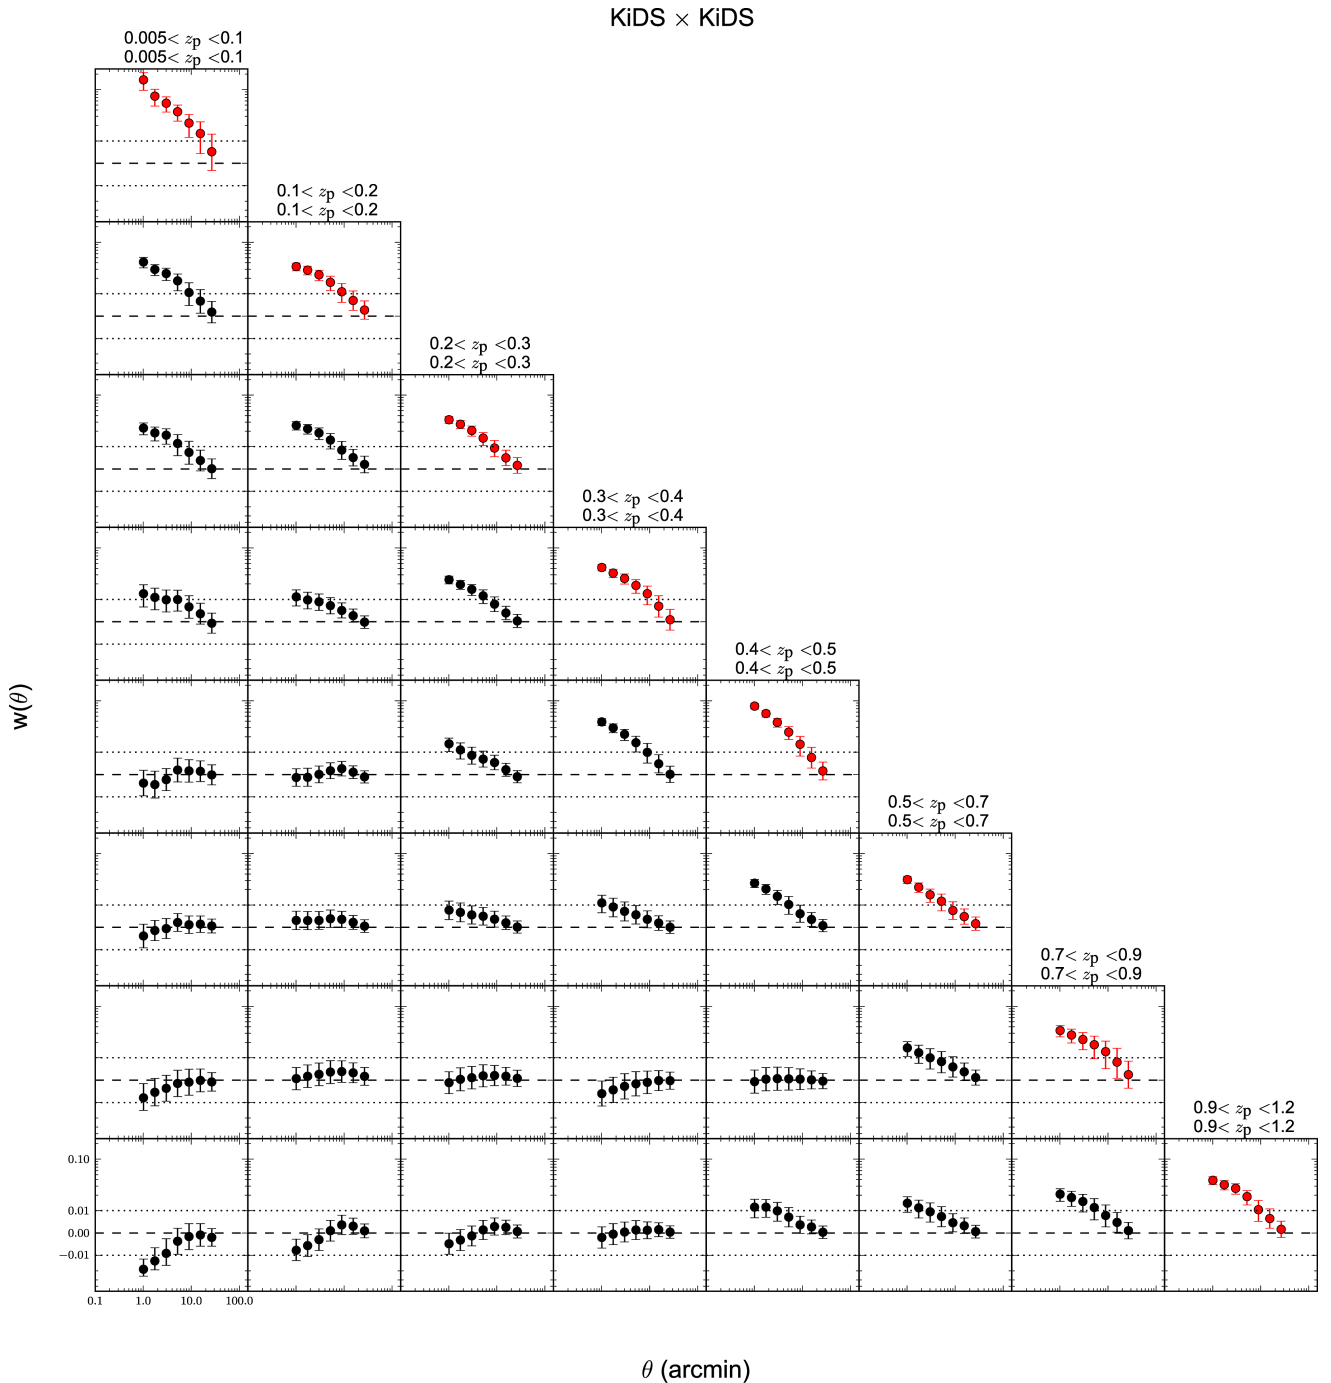

Fig. 21. Angular (cross-)correlation of galaxy positions in different photometric redshift bins in the KiDS-ESO-DR1/2 fields, based on photometric redshifts derived with the BPZ code. Note that the dotted lines at ± 0.01 demarcate a band within which the y -axis is linear. Only unmasked galaxies with extinction-corrected magnitudes brighter than $r = 24$ and $\text{IMAFLAGS_ISO} = 1$ are included. The errors are obtained from jackknife resampling, with each pointing being a jackknife sub-sample. The strongest signals are seen along the diagonal panels and drop off in amplitude for more widely separated photometric redshift bins, which gives confidence in the quality of the photometric redshifts as well as the underlying photometry.

- stellar population properties (Bruzual & Charlot 2003);
- structural parameters and colour gradients.

This will be one of the first samples of this depth over such a large area and wavelength coverage, allowing us to extend previous analyses (e.g. La Barbera et al. 2010) to higher redshifts.

From the KiDS-ESO-DR1/2 catalogues we select galaxies based on the S/G separation discussed in Sect. 4.5 with additional selection criteria on size (to further reduce contamination by stars), and remove any flagged or masked objects. For

KiDS-ESO-DR1/2 this results in a sample of ~ 6.5 million galaxies. For ~ 1 million of these we have measured photometric redshifts as discussed in Sect. 6.2. For the structural parameter derivation we have considered only galaxies with high r -band S/N ($S/N_r > 50$) to reliably perform the surface brightness analysis (La Barbera et al. 2008, 2010). This sub-sample consists of around 350 000 galaxies. The completeness of the whole sample has been discussed in Sect. 5.4. For the sample with photometric redshifts the 98% completeness magnitudes (all magnitudes used here are MAG_AUTO) are $u = 22.3$, $g = 22.1$,

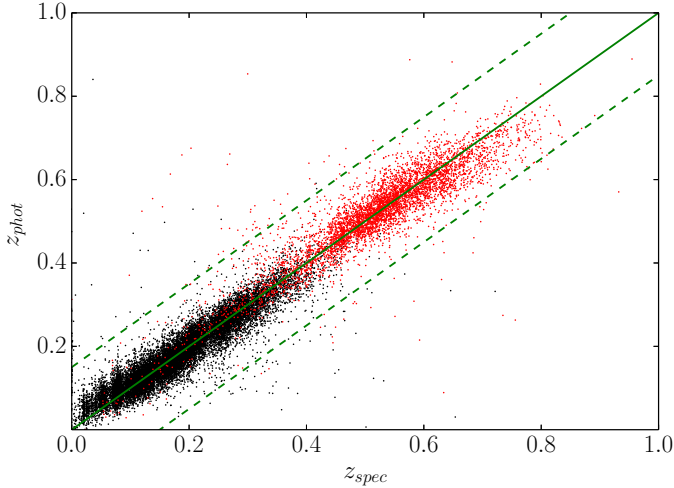

Fig. 22. The z_{phot} vs. z_{spec} scatter plot of the blind test set KiDS-based optical photometric redshifts against the GAMA (black dots) and SDSS (red dots) spectroscopic redshifts, where the photometric redshifts have been obtained with the MLPQNA model. The dotted lines are the borders delimiting the catastrophic outlier sub-regions (i.e. including objects with $|\Delta z_{\text{norm}}| > 0.15$).

$r = 20.4$ and $i = 19.7$, which correspond to 90% completeness magnitudes of $u = 23.1$, $g = 23.0$, $r = 22.1$ and $i = 21.2$. The stringent cuts on S/N for the sample with structural parameters results in 98% completeness magnitudes of $u = 21.4$, $g = 21.1$, $r = 20.1$, $i = 19.3$ and 90% completeness magnitudes of $u = 22.2$, $g = 21.7$, $r = 21.0$, $i = 20.2$. These completeness magnitudes can be converted to absolute magnitudes as $M = m - DM(z_{\text{phot}}) - K_{\text{corr}}$, where $DM(z_{\text{phot}})$ is the distance modulus based on the photometric redshift and K_{corr} is the K -correction, which is derived for two empirical models (elliptical and Scd galaxy). For these calculations a standard cosmology with $\Omega_{\text{m}} = 0.3$, $\Omega_{\Lambda} = 0.7$ and $H_0 = 75 \text{ km s}^{-1} \text{ Mpc}^{-1}$ is used, and the galactic foreground extinction is corrected based on the dust maps from Schlegel et al. (1998). Figure 23 shows how the 90% completeness limits vary with absolute magnitude as a function of redshift. Comparing this to the M^* from the luminosity function of low- z SDSS galaxies (Blanton et al. 2005) we find that M^* is reached at $z \sim 0.22, 0.31, 0.42$, and 0.42 in our high-S/N galaxy sample and $z \sim 0.27, 0.44, 0.53$, and 0.57 for the photo- z sample, in u, g, r and i , respectively, if the Elliptical model is adopted. Slightly larger redshifts are found for late-type galaxies (see Fig. 23).

We make use of GALFIT (Peng et al. 2010) and 2DPHOT (La Barbera et al. 2008) to fit PSF convolved Sérsic profiles to the surface photometry and infer the structural parameters (Sérsic index, n , effective radius R_e , axial ratio, q , disky/boxy coefficient a_4 , disk/bulge separation). In Fig. 24 we show an example of the results obtained with 2DPHOT. The relationship between R_e or Sérsic index and mass, luminosity and its evolution with redshift has been demonstrated to be a fundamental probe of galaxy evolution and the role of mass accretion in galaxy merging (Trujillo et al. 2007; Hilz et al. 2013; Tortora et al. 2014). This characterization of 2D light profiles also allows one to determine the colour gradients (La Barbera & de Carvalho 2009; Tortora et al. 2010a, 2011a; La Barbera et al. 2011, 2012; Tortora & Napolitano 2012), which can be compared to simulations (e.g. Tortora et al. 2011b, 2013).

The resulting data set is introduced in Tortora et al. (2015) and applied to a first census of compact galaxies, a special class

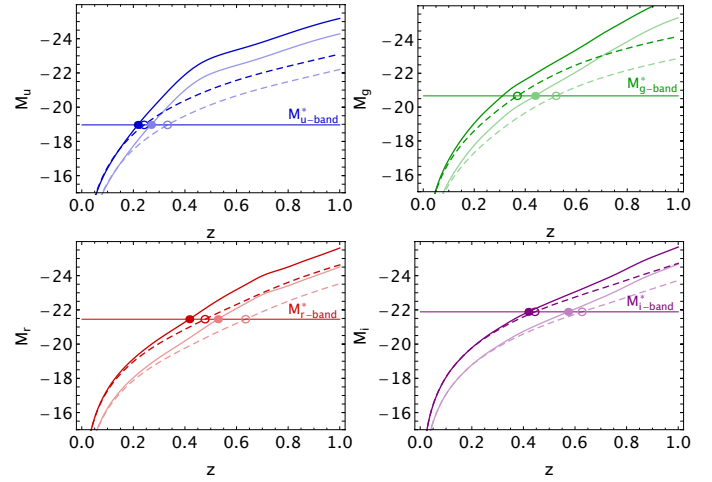

Fig. 23. 90% completeness of the photo- z (lighter colours) and high-S/N (darker colours) galaxy samples in absolute magnitude vs. redshift. Solid and dashed lines are for K -corrections from Elliptical and Scd models. Horizontal lines indicate M^* from the luminosity function analysis in Blanton et al. (2005).

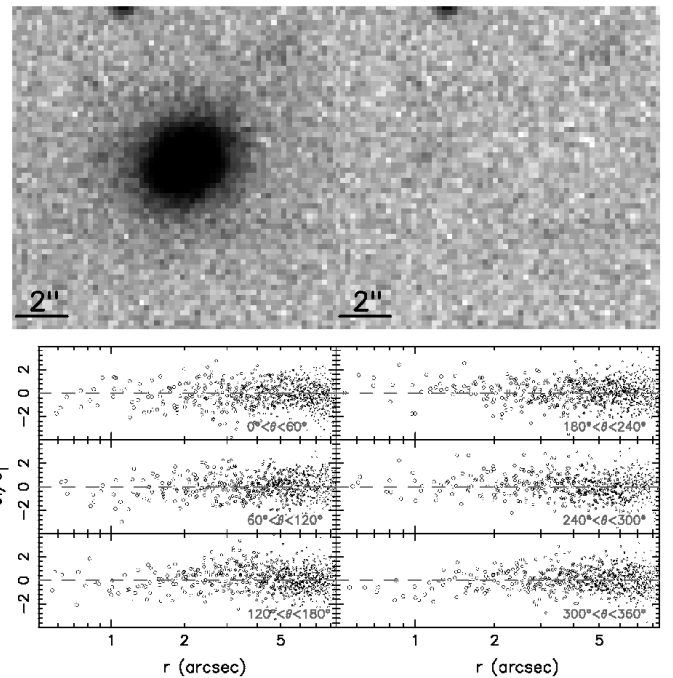

Fig. 24. Example of galaxy surface photometry fitting using 2DPHOT. *Top:* the thumbnail of an original KiDS r -band image with a galaxy in the center is shown on the left, and on the right the same thumbnail after subtracting the best-fit model. *Bottom:* normalized residuals after model subtraction, $\delta I / \sigma_I$, are plotted as function of the distance from the galaxy center. Each subpanel corresponds to a different bin of the polar angle, θ , measured counterclock-wise from the positive x -axis. The residuals, normalized by the noise expected from the model in each pixel, σ_I , are remarkably consistent with zero for all positions in the image, implying a reduced χ^2 of about one.

of objects, relic remnants of high- z red nuggets, which can provide significant constraints on the galaxy merging history. The full analysis of the galaxy sample discussed above will be presented in Napolitano et al. (in prep.).

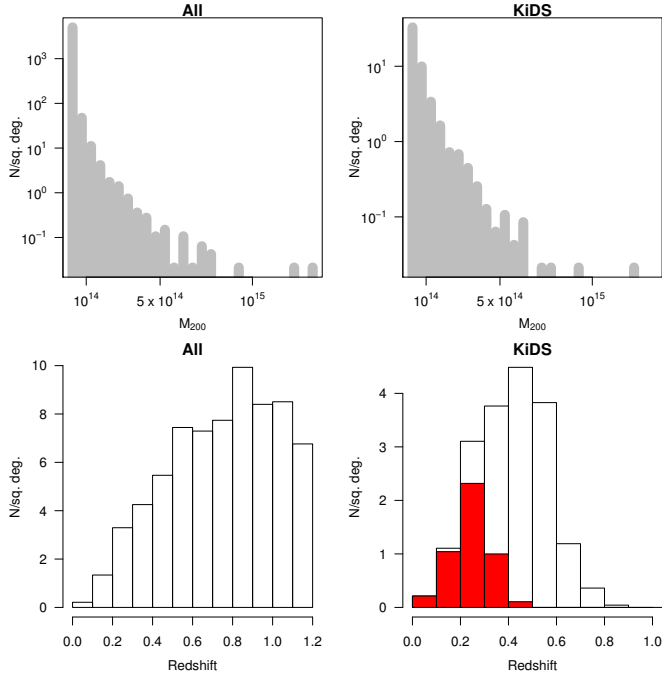

Fig. 25. *Top:* mass distribution of clusters in the H12 catalogues in the redshift range $0 < z < 1$, before (*left*) and after (*right*) the selection based on the KiDS *gri* limiting magnitudes. *Bottom:* redshift distribution; in the *lower right panel*, the results obtained using the SDSS magnitude limits are displayed for comparison (red histogram).

6.4. Galaxy cluster detection

The evolution of the number density of massive galaxy clusters is an important cosmological probe (e.g. Allen et al. 2011), particularly at high redshifts ($z > 0.5$). It is therefore important to increase the number of known galaxy clusters. The number of clusters as a function of mass and redshift detected in a KiDS-like survey was evaluated using the mock catalogues derived by Henriques et al. (2012, H12 hereafter), which are based on the semi-analytic galaxy models built by Guo et al. (2011) for the Millennium Simulation (MS; Springel et al. 2005). In particular, these mock catalogues provide SDSS *ugri* photometry for galaxies in 24 light cones, $1.4 \times 1.4 \text{ deg}^2$ each, as well as the M_{200} mass of their parent halos. Galaxy clusters were identified in the mock catalogues following the recipe by Milkeraitis et al. (2010, see their Table 1): cluster members were defined as those with the same friends-of-friends identification number and M_{200} of their parent halo, and clusters with less than five members were rejected. Next, galaxies with *gri* magnitudes brighter than the KiDS limiting magnitudes (see Fig. 9) were selected: we further considered only those clusters with at least 10 galaxies after the latter selection.

Figure 25 shows the mass and redshift distribution of the simulated clusters in H12 before (left) and after (right) the KiDS magnitude cuts were applied: it can be seen that a KiDS-like survey can probe galaxy clusters in the $z \sim 0.4\text{--}0.8$ redshift range, extending the cluster detection studies based on SDSS data, which are incomplete beyond $z \sim 0.35$ (e.g. Rykoff et al. 2014; Rozo et al. 2014). For comparison, in the lower right panel we overplot the redshift distribution obtained adopting the SDSS limiting magnitudes ($i < 21 \text{ mag}$, $gr < 22 \text{ mag}$), showing the improvement expected with KiDS for $z > 0.4$. At the moment, a cluster detection analysis is on-going (Radovich et al. 2015) using the methods described in Bellagamba et al. (2011), which

are based on an optimal filter to find galaxy overdensities from the position, photometry and possibly also photometric redshift of the galaxies in the catalogues. Details and first results will be discussed in a separate paper.

6.5. High-redshift quasar searches

High redshift quasars are direct probes of the Universe less than 1 Gyr ($z > 5.7$) after the Big Bang. They provide fundamental constraints on the formation and growth of the first supermassive black holes (SMBHs), on early star formation, and on the chemical enrichment of the initially metal-free intergalactic and interstellar medium. The existing ensemble of high-redshift QSOs is dominated by luminous objects with exceptionally high accretion rates (close to Eddington) and very large SMBHs ($\sim 10^9 M_{\odot}$). For several reasons it is needed to probe fainter QSOs, well below the “tip of the iceberg”. This would allow to test SMBH early growth scenarios, which can predict a more common population of faint QSOs (Costa et al. 2014) with lower accretion rates. Furthermore, it would allow a better study of the symbiosis in growth of SMBHs and their stellar hosts over cosmic time. These are hampered currently by potentially severe selection biases when comparing AGN-selected samples at high redshift to the host selected samples at low redshift (Willot et al. 2005; Lauer et al. 2007).

For these reasons we are building up a homogeneous sample of QSOs at $5.7 < z < 6.4$ by combining KiDS and VIKING and using the *i*-band drop-out technique. The 9-band *u* through K_s photometry from the combined surveys goes up to $\sim 2 \text{ mag}$ deeper than SDSS, UKIDSS and the Panoramic Survey Telescope & Rapid Response System 1 (Pan-STARRS1; Bañados et al. 2014). So far we have discovered nine such QSOs, where the first four are published in Venemans et al. (2015). KiDS is also a useful ingredient in the detection of very high redshift ($z > 6.4$) QSOs with VIKING. Adding the *i*-band KiDS data in the photometric selection removes $\sim 50\%$ of these Z-band drop-out candidates (Venemans et al. 2013).

6.6. Strong gravitational lens searches

Strong gravitational lensing provides the most accurate and direct probe of mass in galaxies, groups and clusters of galaxies (Bolton et al. 2006; Tortora et al. 2010b). The deep, subarcsecond seeing KiDS images are particularly suitable for a systematic census of lenses based on the identification of arc-like structures around massive galaxies, galaxy groups and galaxy clusters. The angular size of the Einstein ring θ_E can be expressed as function of the velocity dispersion σ_v as (Schneider et al. 1992):

$$\theta_E \sim 1'' \times \frac{D_{\text{ds}}}{D_s} \frac{\sigma_v}{220 \text{ kms}^{-1}}, \quad (8)$$

where D_{ds} and D_s are the angular diameter distance between the lens and source and to the source, respectively. For a typical $FWHM \sim 0.7''$ in *r*-band, we can expect to detect lensing arcs of gravitational structures with $\sigma_v > 180 \text{ kms}^{-1}$.

A first search was based on visual inspection. A sample of lens candidates was selected with the following two simple selection criteria, using the photometric redshifts described in Sect. 6.2 and the KiDS-ESO-DR1/2 *r*-band source lists. These criteria are aimed at maximising the lensing probability for the KiDS photometric sensitivities: 1) $0.1 < z_{\text{phot}} < 0.5$ and 2) $r < 20$. Candidates are visually assessed by inspecting colour images and *r*-band images where the galaxy model obtained with

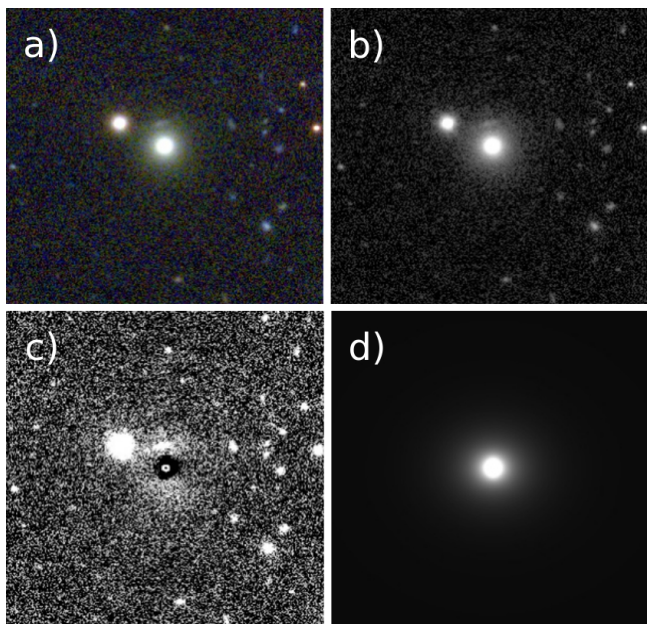

Fig. 26. Example of strong lensing candidate identified in KiDS. **a)** Colour image; **b)** r -band image; **c)** r -band image after subtraction of 2DPHOT galaxy model; **d)** 2DPHOT galaxy model. A faint blue arc is visible above the central galaxy and is clearly detected after model subtraction.

2DPHOT (see Sect. 6.3) is subtracted. In a control set of 600 candidates in the area overlapping with SDSS, 18 potential lens candidates were identified, half of which have high significance (Napolitano et al. 2015). An example of a good lens candidate is shown in Fig. 26. Another approach consists of automatic selection of lens candidates by filtering the KiDS-ESO-DR1/2 multi-band catalogues for massive early-type galaxies. This is done using colour-colour cuts and automated SED classifiers. In addition, candidates of strongly lensed quasars are identified based on colour and morphology. Candidates from both approaches have been selected further via visual inspection and are being followed up for spectral confirmation.

In the future, as the data volume grows, searches for strong lenses in large-area surveys such as KiDS will have to be performed with (semi-)automated techniques (Alard 2006; More et al. 2012; Gavazzi et al. 2014; Joseph et al. 2014), as the numbers of typical host galaxy candidates can be of the order of thousands per square degree, rendering visual inspection prohibitive. However, current automatic lens-finding tools are not perfect and all automated techniques are still being tested on simulated data (e.g. Metcalf & Petkova 2014; Gavazzi et al. 2014).

7. Summary and outlook

The Kilo-Degree Survey is a 1500 square degree optical imaging survey in four filters ($ugri$) with the VLT Survey Telescope. Together with its near-infrared sister survey VIKING, a nine-band $ugriZYJHK_s$ optical-infrared data set will be produced. While KiDS was primarily designed as a tomographic weak gravitational lensing survey, many secondary science cases are pursued.

In this paper the first two data releases (KiDS-ESO-DR1 and KiDS-ESO-DR2) are presented, comprising a total of 148 survey tiles, or ~ 160 square degrees. The data products of these two public data releases were produced using a fine-tuned version of

the ASTRO-WISE optical pipeline (McFarland et al. 2013), complemented with the automated PULECENELLA masking software and the KiDS-CAT source extraction software. Data products include calibrated stacked images, weight maps, masks, source lists, and a multi-band source catalogue. Data can be accessed through the ESO Science Archive, the ASTRO-WISE system, and the KiDS website (see Sect. 2.6 for the relevant links).

The achieved data quality is very close to expectations, with a very small PSF ellipticity over the full FOV and typical limiting magnitudes (5σ AB in $2''$ aperture) of 24.3, 25.1, 24.9 and 23.8 in u , g , r and i , respectively. As the designated lensing band, r -band receives the best dark seeing conditions, resulting in an median PSF size of $\sim 0.65''$, with PSF size variations over the FOV usually $< 15\%$. Within survey tiles, the photometry is stable to $\sim 2\%$, but since the photometric calibration is performed using nightly zero-points, photometric offsets between tiles are present due to extinction variations; this will be improved in future data releases. The multi-band source catalogue provided is based on detection in r -band and 98% complete to $r \approx 24.0$.

Early weak-lensing applications (Sifón et al. 2015; Viola et al. 2015; van Uitert et al. 2015) of KiDS data rely on the KiDS-ESO-DR1 and -DR2 data products presented here for photometric redshifts, while galaxy shape measurements are based on a dedicated pipeline (see Erben et al. 2013; Miller et al. 2013). Other applications of KiDS-ESO-DR1 and -DR2 data include galaxy structural parameter studies, cluster detection, strong gravitational lens detection, and high-redshift QSO searches. The latter has resulted in the detection of nine $5.7 < z < 6.4$ QSOs to date (Venemans et al., in prep.).

Future data releases, apart from adding more survey tiles to the currently covered area, are foreseen to include additional, value-added data products. During the first years of survey operations the observational data rate has been hampered by several factors, causing slower progress than anticipated. Together with ESO the KiDS team has been working on various improvements, which has led to a significant increase in survey speed since early 2014. At the current rate the survey is expected to be completed by 2019, but continuing efforts to enhance telescope and operational efficiency are expected to lead to further improvements.

Acknowledgements. Based on data products from observations made with ESO Telescopes at the La Silla Paranal Observatory under programme IDs 177.A-3016, 177.A-3017 and 177.A-3018, and on data products produced by Target/OmegaCEN, INAF-OACN, INAF-OAPD and the KiDS production team, on behalf of the KiDS consortium. Appendix A: Single-band source list columns

The following table lists the columns that are present in the single-band source lists provided in KiDS-ESO-DR1/2. Note that of the 27 aperture flux columns only the ones for the smallest aperture (2 pixels, or 0.4'' diameter) and the largest aperture (200 pixels, or 40'' diameter) are listed. Note: the label for the aperture of 28.5 pixels is FLUX_APER_28p5.

Table A.1. Columns provided in the single-band source lists.

Label	Format	Unit	Description
2DPHOT	J	Source	classification (see section on star/galaxy separation)
X_IMAGE	E	pixel	Object position along x
Y_IMAGE	E	pixel	Object position along y
NUMBER	J		Running object number
CLASS_STAR	E		SEXTRACTOR S/G classifier
FLAGS	J		Extraction flags
IMAFLAGS_ISO	J		FLAG-image flags summed over the iso. profile
NIMAFLAG_ISO	J		Number of flagged pixels entering
IMAFLAGS_ISO	J		Number of flagged pixels entering IMAFLAGS_ISO
FLUX_RADIUS	E	pixel	Fraction-of-light radii
KRON_RADIUS	E	pixel	Kron apertures in units of A or B
FWHM_IMAGE	E	pixel	FWHM assuming a Gaussian core
ISOAREA_IMAGE	J	pixel ²	Isophotal area above Analysis threshold
ELLIPTICITY	E		$1 - B_IMAGE/A_IMAGE$
THETA_IMAGE	E	deg	Position angle (CCW/x)
MAG_AUTO	E	mag	Kron-like elliptical aperture magnitude
MAGERR_AUTO	E	mag	rms error for AUTO magnitude
ALPHA_J2000	D	deg	Right ascension of barycenter (J2000)
DELTA_J2000	D	deg	Declination of barycenter (J2000)
FLUX_APER_2	E	count	Flux vector within circular aperture of 2 pixels
...
FLUX_APER_200	E	count	Flux vector within circular aperture of 200 pixels
FLUXERR_APER_2	E	count	rms error vector for flux within aperture of 2 pixels
...
FLUXERR_APER_200	E	count	rms error vector for flux within aperture of 200 pixels
MAG_ISO	E	mag	Isophotal magnitude
MAGERR_ISO	E	mag	rms error for isophotal magnitude
MAG_ISOCOR	E	mag	Corrected isophotal magnitude
MAGERR_ISOCOR	E	mag	rms error for corrected isophotal magnitude
MAG_BEST	E	mag	Best of MAG_AUTO and MAG_ISOCOR
MAGERR_BEST	E	mag	rms error for MAG_BEST
BACKGROUND	E	count	Background at centroid position
THRESHOLD	E	count	Detection threshold above background
MU_THRESHOLD	E	arcsec ⁻²	Detection threshold above background
FLUX_MAX	E	count	Peak flux above background
MU_MAX	E	arcsec ⁻²	Peak surface brightness above background
ISOAREA_WORLD	E	deg ²	Isophotal area above Analysis threshold
XMIN_IMAGE	J	pixel	Minimum x -coordinate among detected pixels
YMIN_IMAGE	J	pixel	Minimum y -coordinate among detected pixels
XMAX_IMAGE	J	pixel	Maximum x -coordinate among detected pixels
YMAX_IMAGE	J	pixel	Maximum y -coordinate among detected pixels
X_WORLD	D	deg	Baryleft position along world x axis
Y_WORLD	D	deg	Baryleft position along world y axis
XWIN_IMAGE	E	pixel	Windowed position estimate along x
YWIN_IMAGE	E	pixel	Windowed position estimate along y
X2_IMAGE	D	pixel ²	Variance along x
Y2_IMAGE	D	pixel ²	Variance along y
XY_IMAGE	D	pixel ²	Covariance between x and y
X2_WORLD	E	deg ²	Variance along X-WORLD (alpha)
Y2_WORLD	E	deg ²	Variance along Y-WORLD (delta)
XY_WORLD	E	deg ²	Covariance between X-WORLD and Y-WORLD
CXX_IMAGE	E	pixel ⁻²	Cxx object ellipse parameter
CYY_IMAGE	E	pixel ⁻²	Cyy object ellipse parameter
CXY_IMAGE	E	pixel ⁻²	Cxy object ellipse parameter
CXX_WORLD	E	deg ⁻²	Cxx object ellipse parameter (WORLD units)
CYY_WORLD	E	deg ⁻²	Cyy object ellipse parameter (WORLD units)
CXY_WORLD	E	deg ⁻²	Cxy object ellipse parameter (WORLD units)

Table A.1. continued.

Label	Format	Unit	Description
A_IMAGE	D	pixel	Profile rms along major axis
B_IMAGE	D	pixel	Profile rms along minor axis
A_WORLD	E	deg	Profile rms along major axis (WORLD units)
B_WORLD	E	deg	Profile rms along minor axis (WORLD units)
THETA_WORLD	E	deg	Position angle (CCW/world- x)
THETA_J2000	E	deg	Position angle (east of north) (J2000)
ELONGATION	E	deg	A_IMAGE/B_IMAGE
ERRX2_IMAGE	E	pixel ²	Variance of position along x
ERRY2_IMAGE	E	pixel ²	Variance of position along y
ERRXY_IMAGE	E	pixel ²	Covariance of position between x and y
ERRX2_WORLD	E	deg ²	Variance of position along X-WORLD (alpha)
ERRY2_WORLD	E	deg ²	Variance of position along Y-WORLD (delta)
ERRXY_WORLD	E	deg ²	Covariance of position X-WORLD/Y-WORLD
ERRCXX_IMAGE	E	pixel ⁻²	Cxx error ellipse parameter
ERRCYY_IMAGE	E	pixel ⁻²	Cyy error ellipse parameter
ERRCXY_IMAGE	E	pixel ⁻²	Cxy error ellipse parameter
ERRCXX_WORLD	E	deg ⁻²	Cxx error ellipse parameter (WORLD units)
ERRCYY_WORLD	E	deg ⁻²	Cyy error ellipse parameter (WORLD units)
ERRCXY_WORLD	E	deg ⁻²	Cxy error ellipse parameter (WORLD units)
ERRA_IMAGE	E	pixel	rms position error along major axis
ERRB_IMAGE	E	pixel	rms position error along minor axis
ERRA_WORLD	E	deg	World rms position error along major axis
ERRB_WORLD	E	deg	World rms position error along minor axis
ERRTHETA_IMAGE	E	deg	Error ellipse position angle (CCW/ x)
ERRTHETA_WORLD	E	deg	Error ellipse position angle (CCW/world- x)
ERRTHETA_J2000	E	deg	J2000 error ellipse pos. angle (east of north)
FWHM_WORLD	E	deg	FWHM assuming a gaussian core
ISO0	J	pixel ²	Isophotal area at level 0
ISO1	J	pixel ²	Isophotal area at level 1
ISO2	J	pixel ²	Isophotal area at level 2
ISO3	J	pixel ²	Isophotal area at level 3
ISO4	J	pixel ²	Isophotal area at level 4
ISO5	J	pixel ²	Isophotal area at level 5
ISO6	J	pixel ²	Isophotal area at level 6
ISO7	J	pixel ²	Isophotal area at level 7
SLID	K		Source list ID
SID	K		Source ID within the source list
HTM	K		Hierarchical Triangular Mesh (level 25)
FLAG	K		Not used

Appendix B: Multi-band catalogue

The following table lists the columns that are present in the multi-band catalog provided in KiDS-ESO-DR2.

Table B.1. Columns provided in the multi-band catalogue.

Label	Format	Unit	Description
Measurements based on <i>r</i> -band detection image			
ID	23A		Source identifier
RAJ2000	D	deg	Right ascension (J2000)
DecJ2000	D	deg	Declination (J2000)
SG2DPHOT	K		Source classification
A	D	pixel	Linear semi major axis
B	D	pixel	Linear semi minor axis
CLASS_STAR	E		SEXTRACTOR star/galaxy classifier
KRON_RADIUS	E	pixel	Kron-radius used for MAG_AUTO
POSANG	E	deg	Position angle
SEQNR	K		<i>r</i> -band sequence number
Measurements provided for each filter			
FLUXERR_APER_100_<filter>	E	count	flux error in 100 pixel aperture
FLUXERR_APER_10_<filter>	E	count	flux error in 10 pixel aperture
FLUXERR_APER_14_<filter>	E	count	flux error in 14 pixel aperture
FLUXERR_APER_25_<filter>	E	count	flux error in 25 pixel aperture
FLUXERR_APER_40_<filter>	E	count	flux error in 40 pixel aperture
FLUXERR_APER_4_<filter>	E	count	flux error in 4 pixel aperture
FLUXERR_APER_6_<filter>	E	count	flux error in 6 pixel aperture
FLUXERR_APERCOR_100_<filter>	E	count	corrected flux error in 100 pixel aperture
FLUXERR_APERCOR_10_<filter>	E	count	corrected flux error in 10 pixel aperture
FLUXERR_APERCOR_14_<filter>	E	count	corrected flux error in 14 pixel aperture
FLUXERR_APERCOR_25_<filter>	E	count	corrected flux error in 25 pixel aperture
FLUXERR_APERCOR_40_<filter>	E	count	corrected flux error in 40 pixel aperture
FLUXERR_APERCOR_4_<filter>	E	count	corrected flux error in 4 pixel aperture
FLUXERR_APERCOR_6_<filter>	E	count	corrected flux error in 6 pixel aperture
FLUX_APER_100_<filter>	E	count	flux in 100 pixel aperture
FLUX_APER_10_<filter>	E	count	flux in 10 pixel aperture
FLUX_APER_14_<filter>	E	count	flux in 14 pixel aperture
FLUX_APER_25_<filter>	E	count	flux in 25 pixel aperture
FLUX_APER_40_<filter>	E	count	flux in 40 pixel aperture
FLUX_APER_4_<filter>	E	count	flux in 4 pixel aperture
FLUX_APER_6_<filter>	E	count	flux in 6 pixel aperture
FLUX_APERCOR_100_<filter>	E	count	corrected flux in 100 pixel aperture
FLUX_APERCOR_10_<filter>	E	count	corrected flux in 10 pixel aperture
FLUX_APERCOR_14_<filter>	E	count	corrected flux in 14 pixel aperture
FLUX_APERCOR_25_<filter>	E	count	corrected flux in 25 pixel aperture
FLUX_APERCOR_40_<filter>	E	count	corrected flux in 40 pixel aperture
FLUX_APERCOR_4_<filter>	E	count	corrected flux in 4 pixel aperture
FLUX_APERCOR_6_<filter>	E	count	corrected flux in 6 pixel aperture
FLUX_RADIUS_<filter>	E	pixel	SEXTRACTOR FLUX_RADIUS
FWHM_IMAGE_<filter>	E	pixel	SEXTRACTOR FWHM_IMAGE
FLAG_<filter>	J		SEXTRACTOR extraction flag
IMAFLAGS_ISO_<filter>	J		Mask flag
MAGERR_AUTO_<filter>	E	mag	rms error for MAG_AUTO
MAGERR_ISO_<filter>	E	mag	rms error for MAG_ISO
MAG_AUTO_<filter>	E	mag	Kron-like elliptical aperture magnitude
MAG_ISO_<filter>	E	mag	Isophotal magnitude
NIMAFLAGS_ISO_<filter>	J		Number of masked pixels entering IMAFLAGS_ISO
ISOAREA_IMAGE_<filter>	J	pixel ²	Isophotal aperture
XPOS_<filter>	E	pixel	X pixel position <filter> coadd
YPOS_<filter>	E	pixel	Y pixel position <filter> coadd
