17 **Summary:** *As we decarbonise societies, we need to consider how such transitions interconnect energy*  
18 *and transport systems. In this Commentary, we argue that we need a better understanding of who may*  
19 *be vulnerable in low-carbon transitions. Current energy poverty definitions and metrics focus*  
20 *overwhelmingly on energy service consumption within the home, yet similar issues in the transport*  
21 *sector are often neglected. Failure to account for the intersections between energy and transport*  
22 *poverty may deepen structural forms of deprivation and worsen social and material inequalities,*  
23 *therefore preventing equitable transitions.*

24  
25 **Keywords:** energy poverty, fuel poverty, transport poverty, low-carbon transitions, justice

## 26 Introduction

27  
28  
29 There is an urgent need to decarbonise domestic energy and transport if we are to address climate  
30 change. This must, however, be done in a way that avoids worsening inequality; by reducing the most  
31 carbon intensive forms of consumption that cause the most emissions, while also paying attention to  
32 the differentiated impacts for those who are vulnerable in society. Energy poverty generally refers to  
33 the inability to attain socially and materially necessitated levels of domestic energy services,<sup>1</sup> such as  
34 heating, lighting and hot water. Yet, while much research has focused on domestic energy poverty,  
35 significantly less attention has been paid to ‘transport poverty’, i.e. the inability to attain socially and  
36 materially necessitated levels of transport services.<sup>2</sup> Energy and transport services have direct impacts  
37 on people’s wellbeing, life chances and the ability to fully participate in society. Living in energy  
38 poverty, for example, can mean not having access to or being able to afford the required technologies  
39 or appliances to keep a home at a comfortable temperature or cook hot meals. Someone experiencing  
40 transport poverty, meanwhile, may not be able to afford or access essential transport services,  
41 restricting their ability to travel for fundamental needs, such as employment, education or healthcare.<sup>2</sup>

42 Energy and transport poverty have largely been treated in isolation from one another in both research  
43 and policy, and are often seen as having their own causes and consequences. Almost all energy  
44 poverty studies, for example, have focused on domestic energy services, even though the ability to use  
45 energy for transport is also vitally important to wellbeing and life chances. While not all aspects of  
46 transport poverty are directly related to energy consumption, many of them are, and yet they remain  
47 largely overlooked in energy poverty debates. This could be reflective of entrenched disciplinary  
48 boundaries, whereby energy research sees ‘energy demand’ as something that occurs inside the home  
49 (or the office etc.), while the consumption of motor fuel, for example, falls under a separate ‘transport  
50 studies’ tradition. Similarly, the governance of energy and transport has traditionally taken place  
51 through distinct policy areas, jurisdiction, budgets, and R&D projects, with limited capacity to design  
52 and implement overarching policies across different departments. This siloed approach contributes to  
53 different scholars and policy makers focusing on each of these domains, with the connections and  
54 similarities between them often missed.

55 In this Commentary, we argue, first, that as we decarbonise societies, such transitions<sup>3</sup> can mean new  
56 forms of integration between domestic energy and transport systems – with implications for  
57 domestic energy and transport poverty. We also argue that to develop equitable low-carbon societies,<sup>4</sup>  
58 we need better recognition of those acutely vulnerable groups that are at greatest risk of experiencing  
59 *both* energy and transport poverty simultaneously, and of the way the two issues are interlinked. It is  
60 therefore vital to break down traditional disciplinary silos to conduct research, and develop policy,  
61 that helps better understand, and address, these linkages.

## 62 **Intersections between energy poverty and transport poverty**

63 Taken together, the household and transport sectors consumed 56.6% of the final energy in the EU-28  
64 in 2018 and low-carbon transitions are likely to see increased integration and connection between  
65 energy and transport systems. There are several reasons why we should not neglect transport poverty  
66 in energy poverty debates—here we focus specifically on affordability and access.

67  
68 As different indicators are used in different countries, there is no single statistic to show how many  
69 people live in energy and transport poverty. Europe has some level of comparative statistics available  
70 on expenditure and consumption. In 2018, on average EU households spent 13.2% of their income on  
71 transport and 24% on housing, water, electricity, gas and other fuels.<sup>5</sup> The average share of household  
72 expenditure on the ‘operation of personal transport equipment’ is higher than that on ‘electricity, gas  
73 and other fuels’ within the home in the majority of the EU-28 (6.5% vs. 3.9%).<sup>5</sup> Based on official  
74 statistics, an estimated 44.5 million people lived in energy poverty in the European Union in 2016  
75 (EU).<sup>6</sup> Yet analogous statistics for transport poverty do not exist, illustrating how transport  
76 affordability issues are not widely recognised. While EU countries are increasingly adopting official  
77 indicators of energy poverty, currently France is the only EU member state with an official transport  
78 poverty indicator. Based on this official measure, an estimated 10.2% of households in France were in  
79 transport poverty in 2014 (vs. 14.6% in energy poverty),<sup>7</sup> but alternative indicators suggest that  
80 transport poverty may well affect an even greater number of French households (21%) than energy  
81 poverty (18%).<sup>8</sup>

82  
83 In terms of affordability, public debates on energy and transport costs loom large in many countries,  
84 especially as carbon taxes, which may mean higher fuel prices that affect the cost of both energy and  
85 transport services, are introduced. This was demonstrated, for example, by the 2018-2019 Yellow  
86 Vests movement in France (see Figure 1) which originated as a protest against fuel price increases  
87 introduced as part of climate change policies. The disproportionate impact of rises in fuel prices on  
88 low income households was central to many of the protesters’ concerns, although it quickly grew to  
89 include a wider range of social and political issues. Europe is not unique in facing such protests. The  
90 Myanmar government removed state subsidies on natural gas and diesel in 2007, leading to a  
91 doubling of domestic prices for bus fares and automobile fuel which later spilled over into an increase  
92 in the price of basic commodities such as rice, beef, fish, milk, and eggs - hitting rural and poor  
93 households the hardest, and leading to protests and a reactive state crackdown involving violent  
94 deaths. Plans to raise LPG prices for mobility (used primarily by two-wheeled motorcycles and  
95 scooters) in India in 2000 were later abandoned after they provoked mass demonstrations; in the same  
96 year, farmers boycotted and blockaded petrol stations in the United Kingdom as the price of petrol  
97 had been raised to 80p/litre.

98  
99 ***Figure 1: The 2019 Yellow Vest Protests in Paris, France. The protests affected the capital city for weeks,***  
100 ***with insurance companies paying out 89 million euros (\$100 million) to cover thousands of cases of reported***  
101 ***damage. The government also responded with 38 million euros (\$43 million) financial aid for workers who***  
102 ***had been put on reduced work hours due to the anti-government protests.***

Movements such as these in France, Myanmar, India, and the UK have a strong resonance with the energy community, as climate mitigation measures, such as carbon taxes, ultimately impact household costs for both energy and transport, and typically affect some communities and groups disproportionately. This demonstrates a need for alternative forms of pricing design and related policy implementation that can ensure fairness.<sup>9</sup>

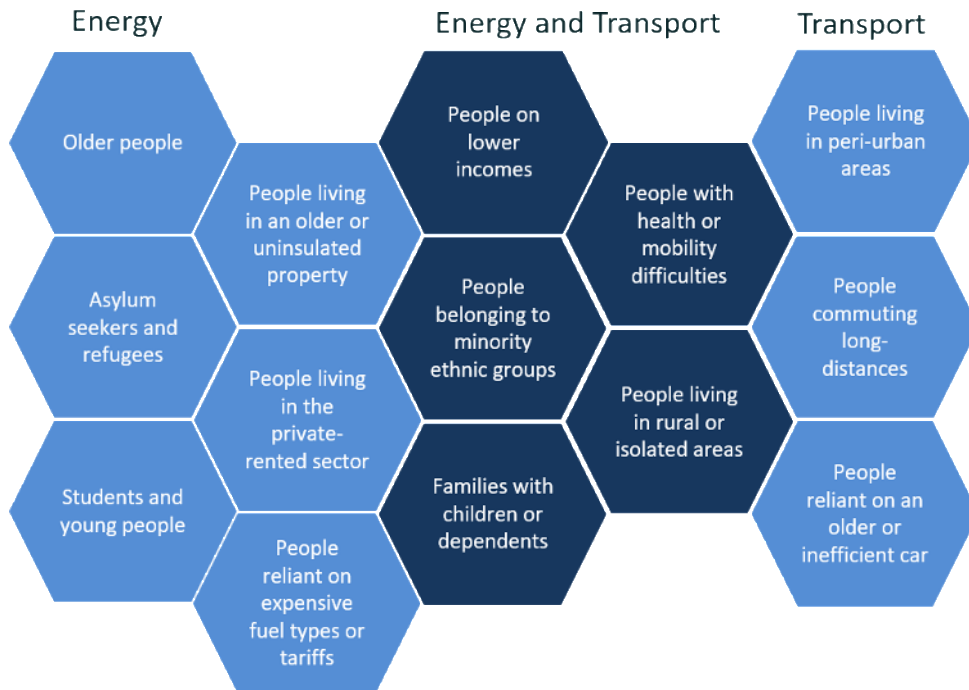

A further overlap between energy and transport poverty is the increasing evidence of a ‘double vulnerability’ phenomenon, whereby some social groups are at greater risk of experiencing poverty of both energy and transport services simultaneously<sup>10, 11</sup> (see Figure 2). Those on low incomes can be hit particularly hard as energy and transport costs take up a greater proportion of their incomes and they often lack financial resources to invest in the most energy efficient appliances or vehicles. Single-parent households, and people belonging to ethnic minority groups can be at greater risk, partly as they tend to be over-represented in low-income groups and may be living in poorer-quality housing with fewer transport options. Households with children can also encounter relatively high energy and transport costs caused by, for example, increased space heating or space cooling demand, greater appliance use, and a higher frequency of journeys to transport children which often induces car ownership. Those with chronic health conditions, disabilities or mobility problems have a higher likelihood of experiencing both energy and transport poverty simultaneously, due to lower incomes combined with increased energy and transport requirements. These can include, for example, a combined need for keeping higher room temperatures, running medical equipment, and making frequent trips to medical services. Finally, living in geographically isolated areas also increases the risk of both energy and transport poverty, primarily due to the need to travel longer distances to access key services and a reliance on expensive domestic energy and motor fuel.

Crucially, for vulnerable households the problem goes beyond simply experiencing energy and transport poverty simultaneously – there are also likely to be mutually reinforcing causal links between the two conditions. In terms of affordability, high transport costs reduce the disposable income people have available to pay for energy bills, and vice versa. For these households, expenditures on energy and transport are often traded off against each other in daily life, and they must either sacrifice spending on transport to pay for home energy services, or ration their energy use to afford journeys that many take for granted.<sup>2,12</sup>

In terms of access, a low-carbon transition could see some households having onsite energy generation and storage technologies coupled with EV chargepoints, thus enabling them to participate in new ‘flexibility’ and ‘vehicle-to-grid’ markets. Who can *access* and *benefit* from such systems, in addition to who can *afford* them, are key questions going forward. A continued neglect of transport poverty in these initiatives could have adverse policy effects, as could, for example, the development of energy-efficient housing in areas where there are limited low-carbon or public transport options, such as car-dependent periurban locations. In such cases, people may be living in newly built homes

147 that consume less energy, but still have to rely on energy-hungry and expensive private transport to  
 148 obtain vital services due to poor access to public transport.<sup>2</sup> In some contexts where racial segregation  
 149 is especially deep-rooted, such as South Africa and parts of the USA, transport and energy poverty  
 150 can also reinforce the spatial marginalisation of minority ethnic groups, who can be relegated to areas  
 151 with both poor transport and housing infrastructure.

152  
 153 **Figure 2: Groups at risk of energy and transport poverty\***

 157

158 **Recommendations and Conclusion**

159 There are substantial connections between energy and transport poverty, with some people and places  
 160 at heightened risk of experiencing both problems simultaneously and in a mutually reinforcing  
 161 manner. Without carefully designed policies to address these as one problem, we run the risk of one  
 162 issue exacerbating the other. This highlights the need for a greater understanding of these links and  
 163 risks, particularly if we are to achieve a just and equitable low-carbon transition and address high  
 164 levels of consumption without causing new vulnerabilities. Previous research has shown that energy  
 165 and transport poverty are not experienced equally, but can affect particular communities and  
 166 geographies more than others. We should pay attention to the spatial and temporal aspects of the role  
 167 of transport within energy poverty debates, and subsequent impacts on life chances across places and  
 168 generations. Further understanding is therefore required, especially on how transport and energy costs  
 169 are traded off against each other in the everyday lives of the most vulnerable in our societies. Future  
 170 research should also examine the co-benefits of energy and transport poverty reduction, and what that  
 171 may mean, for example, for education and employment opportunities.

172 As energy poverty has begun to receive significant policy attention in the UK and the EU, the next  
 173 step for policy makers is to recognise that transport poverty also exists, and that it has an important  
 174 energy dimension. There are few policies that recognise the connections between energy and transport  
 175 systems, but areas and communities that could be exposed to the double vulnerability phenomenon  
 176 would benefit from low-carbon policies that address both energy and transport poverty  
 177 simultaneously. Inevitably, decarbonisation policies and initiatives, be it the rollout of electric  
 178 transport, the creation of new energy efficient housing, or moves towards electrification and domestic  
 179 energy system integration, are relevant to both sectors. Once policymakers have recognised transport  
 180 poverty as an issue, they can move towards more composite and integrative metrics that grapple

181 with its intersections with energy poverty and capture the risk of double vulnerability. This could help  
182 facilitate more targeted policy interventions in the areas and communities that are most susceptible to  
183 this double energy vulnerability we have outlined here. Ultimately, if decarbonisation policies are not  
184 designed effectively to address both energy and transport poverty, there is a risk that policies will be  
185 unable to adapt to new vulnerabilities as they emerge. In building decarbonised societies, we must  
186 ensure that as emissions from homes and transport are simultaneously reduced, they do not come at  
187 the expense of worsening patterns of inequality.
