3  
4  
5  
6 Targeting of G-protein coupled receptors (GPCRs) like somatostatin (SST) could  
7  
8 have a potential interest in delivery of anti-cancer agents to tumor cells. Attachment  
9  
10 of SST to different nano-carriers e.g., polymeric nanoparticles is limited due to the  
11  
12 difficulty of interaction between SST itself and those nano-carriers. Furthermore,  
13  
14 the instability problems associated with the final formulation. Attaching of SST to  
15  
16 gold nanoparticles (AuNPs) using the positive and negative charge of SST and  
17  
18 citrate-AuNPs could be considered a new technique to get stable non-aggregated  
19  
20 AuNPs coated with SST. Different analyses techniques have been performed to  
21  
22 proof the principle of coating between AuNPs and SST. Furthermore, cellular  
23  
24 uptake study on HCC-1809 cell lines has been investigated to show the ability of  
25  
26 AuNPs coated SST to enter the cells via SST receptors. Dynamic light scattering  
27  
28 (DLS) indicated a successful coating of SST on the MUA-AuNPs surface.  
29  
30 Furthermore, all the performed analysis including DLS, SDS-PAGE and UV-VIS  
31  
32 absorption spectra indicated a successful coating of AuNPs with SST. Cellular  
33  
34 uptake study on HCC-1806 cell lines showed that the number of AuNPs-SST per  
35  
36 cell is significantly higher compared to citrate-AuNPs when quantified using  
37  
38 inductively coupled plasma spectroscopy. Moreover, the binding of AuNPs-SST to  
39  
40 cells can be suppressed by addition of antagonist, indicating that the binding of  
41  
42 AuNPs-SST to cells is due to receptor-specific binding. In conclusion, AuNPs  
43  
44 could be attached to SST via adsorption to get stable AuNPs coated SST. This new  
45  
46 formulation has a potential to target SST receptors localized in many normal and  
47  
48 tumor cells.

### Introduction

Gold nanoparticles (AuNPs) are considered to be very important and applicable tool in nanotechnology. This is due to their easy surface functionalization and/ or bio-conjugation, stability and biocompatibility. They have been the subjects of many studies and many applications in medicine and in biology, such as immunoassays, drug targeting of cancer cells and in biomedical research (1-2). AuNPs were delivered to ovarian cancer cells that express the epidermal growth factor receptor and the folate receptor, the ovarian cell took all particles by active transport (3). It was found that tumor cells can be killed by excitation of internalized AuNPs, the internalized AuNPs were excited by laser beam which killed the cancer cells (4).

SSTRs are members of the G-protein coupled receptors (GPCRs) super family (5-6). There are five different subtypes of SSTRs (SSTR1-5), SSTR<sub>2</sub> having been classified into two subtypes, SSTR<sub>2A</sub> and SSTR<sub>2B</sub> (7-8). The blocking of SSTRs with antagonist suppresses the interaction of the peptide agonist with SSTRs (9). SSTRs are present in the surface of numerous normal and diseased cells; they are expressed in normal tissues such as the pituitary gland and pancreas (8, 10). SSTRs are also expressed in many tumor cells i.e. small cell and non-small lung cancer lung cancer (11-13), neuroendocrine tumors and breast cancer (14).

Receptor-mediated endocytosis is an important example of a specific internalization mechanism following ligand binding to their receptor (15-17). It allows for an import of extracellular molecules for around 1000-fold increase of the intracellular concentration of macromolecules (18-20). In the process of endocytosis, the plasma membrane is engulfed inwards from specialized membrane micro-domains forming either clathrin or caveolin-coated pits (20).

1  
2  
3  
4 SST has many functions in mammals, it can controls the secretion of growth  
5  
6 hormones (21). Moreover, it is widely distributed throughout the central nervous  
7  
8 system and peripheral tissues employing numerous roles in the central nervous  
9  
10 system (22-23). Furthermore, SST inhibits the regulation of many endogenous cell  
11  
12 functions, including the modulation of neurotransmission, motility, cell  
13  
14 proliferation and cell secretion (24-25). Hence, SST could be considered promising  
15  
16 molecules in drug delivery applications. The limited stability and the presence of  
17  
18 many functional groups within SST make the interaction with other compounds  
19  
20 such as PEGylation with thiolated-PEG is difficult. Many trials have been  
21  
22 performed in our laboratory for PEGylation of SST or even attaching any other  
23  
24 polymer to coat AuNPs. Such trials showed the difficulty of such attachment due to  
25  
26 the numerous functional groups of SST. Moreover, it may affect the structure and  
27  
28 integrity of SST.  
29  
30  
31

32  
33 Up to date and according to our research in literature we have the first attempt to  
34  
35 rationally develop and formulate a novel stable non-aggregated AuNPs coated with  
36  
37 SST. AuNPs coated with SST system has a potential to active target SST receptors  
38  
39 for diagnostic as well as therapeutic purposes. The novel prepared system utilizing  
40  
41 the absorption between the positively charged SST and the negatively charged  
42  
43 citrate-AuNPs at neutral pH. AuNPs were prepared by citrate reduction method  
44  
45 and coated with 11-MUA to facilitate the binding with SST. Furthermore, the  
46  
47 stability and the ability to adsorb SST to either citrate-coated-AuNPs or 11-MUA-  
48  
49 coated AuNPs were investigated. The prepared citrate-AuNPs, MUA-AuNPs and  
50  
51 AuNPs coated with different concentrations of SST were examined for their size,  
52  
53 polydispersity and surface charge. Moreover, the dissociation and adsorption of  
54  
55 SST to AuNPs were also studied and confirmed using sodium dodecyl sulphate and  
56  
57  
58  
59  
60

1  
2  
3 polyacrylamide gel electrophoresis. Cellular uptake study for citrate-AuNPs,  
4 AuNPs-SST and AuNPs-SST together with antagonist was also performed using  
5 HCC-1806 cell lines. In addition, the amounts of Au internalized into the cells were  
6 quantified using inductively coupled plasma spectroscopy (ICP-OES).

## Materials and methods

### Materials

Somatostatin acetate (SST) was kindly supplied from CuraMED Pharma GmbH (karlsruhe, Germany). Hydrogen tetrachloroaurate tri-hydrate, 11-Mercaptoundecanoic acid (11-MUA), RPMI 1640 medium, bovine serum albumen, Chloroauric acid ( $\text{HAuCl}_4$ ) and cyn-154806 trifluoroacetate (TFA) were purchased from Sigma Aldrich (Steinheim, Germany). Tri-sodium citrate dihydrate, sodium chloride, sodium hydroxide, nitric acid, hydrochloric acid, triethylamine, sodium dihydrogen phosphate, disodium hydrogen phosphate were purchased from Merck (Darmstadt, Germany). Dulbecco's phosphate buffered saline (pH 7.4), Dulbecco's Modified Eagle Medium, and Leibovitzs L-15 were purchased from Invitrogen, (Paisley, UK). Triple negative breast cancers cells (HCC-1806) were kindly supplied from Dr. Abdellatif Bouazzaoui (Haematology and Internal Oncology, Regensburg University, Germany). The purified water used for all experiment was obtained using a Milli-Q water purification system from Millipore (Schwalbach, Germany). Any other chemicals and solvents were of analytical grade.

### Preparation of AuNPs capped with SST

#### Preparation of citrate-AuNPs

First, citrate-AuNPs were prepared according to a previously reported procedure (26-28). Briefly, 3mL of 38.8mM tri-sodium citrate solution were added to 100mL of 0.3mM Chloroauric acid ( $\text{HAuCl}_4$ ) solution in a 250mL round bottom flask. The reaction mixture stirred vigorously and heated under reflux. Refluxing was continued for 15 minutes, and then the prepared AuNPs was left to cool at room temperature (28). Stirring was continued for an additional 15 minutes. AuNPs were purified from larger

2  
3  
4 aggregates by centrifugation for 30 minutes at 2,450 ×g using (Avanti centrifuge J-E/  
5  
6 Beckman coulter GmbH, Germany).  
7  
8

### 9 10 **Stabilization of the synthesized citrate-AuNPs**

11 11-MUA was deposited on the gold surface to facilitate the electrostatic binding  
12 between SST and AuNPs (29-31). Briefly, 1mL of 1mM stock solution of 11-MUA  
13 was added to 20mL of the prepared AuNPs solution in a 100mL Erlenmeyer flask.  
14  
15 After adjusting the pH to 11, the AuNPs were incubated with 11-MUA under  
16 continuous stirring at 600rpm at room temperature overnight. This allows sufficient  
17 exchange of citrate anions with 11-MUA on the particle surface. The stabilized  
18 particles were purified by centrifugation at 15,700×g for 20 minutes in a falcon tube  
19 using an Avanti centrifuge J-E/ Beckman coulter GmbH, Germany. The supernatant  
20 was decanted and the precipitate was resuspended again in Millipore water (30).

### 33 **Coating of MUA-AuNPs with SST**

34 First, different concentrations of SST (20, 40, 60, 100 and 200nM) were studied to  
35 show the optimal concentration for coating. In brief, 3mL of the prepared MUA-  
36 AuNPs were mixed with 100µL of 10mM NaCl as isotonic solution and stirred for 30  
37 minutes(32). Then the stabilized MUA-AuNPs were added drop-wise to 10µL of  
38 different concentrations of SST to determine the optimum concentration of SST that  
39 can load to AuNPs. The solution was stirred for another 30 minutes. The stabilized  
40 AuNPs-SST were purified by centrifugation at 15,700×g for 15 minutes, using  
41 (Eppendorf centrifuge 5415R, Hamburg, Germany), the supernatant was decanted and  
42 the precipitate was re-suspended again in Millipore water. The steps of deposition and  
43 purifications are shown in (Figure 1).

8

9 **Size and surface charge**

10 To determine the size, count rate and zeta potential of AuNPs, the samples were  
11 adjusted to  $25\pm 1.0^\circ\text{C}$  and laser light scattering analysis was performed with an incident  
12 laser beam of 633nm at a scattering angle of  $90^\circ$  using the Malvern zetasizer nano 6.01  
13 (Malvern Instruments GmbH, Herrenberg, Germany). The sampling time was set  
14 automatically. Moreover, three measurements were allowed to perform each 10 sub-  
15 runs and, all measurements were carried out in aqueous solution. The results were  
16 calculated from the average of three independent measurements (28).

28 **Dissociation of SST from AuNPs-SST by solid sodium dodecyl sulfate**

29 Sodium dodecyl sulfate, (SDS) was used to adsorb and dissociate the AuNPs from the  
30 formulated AuNPs-SST leaving SST free in solution. Then, the free SST was  
31 quantified using HPLC. In brief, 3mL of the purified AuNPs-SST were incubated with  
32 3mg solid SDS at room temperature and left overnight. SDS adsorbed the AuNPs from  
33 AuNPs-SST leaving SST free in the supernatant which it can be measured and  
34 identified by HPLC.

45 HPLC analysis was performed for SST using a system with a Degasser (Knauer,  
46 Berlin, Germany), LC-10AT pump, FCV-10ATVP gradient mixer, SIL-10ADVP  
47 autosampler, CTO-6A column oven, SPD-10AV UV-detector, RF-551 fluorescence  
48 detector and SCL-10AVP controller (Shimadzu, Duisburg, Germany). HPLC analysis  
49 was performed for SST using linear gradient method from 26% to 39% acetonitrile in  
50 water, with 0.1% TFA, as mobile phase was applied over 15 minutes at a flow rate of

4 1.0mL/minute. The samples were separated at a temperature of 40°C using a C18-  
5  
6 reversed Precolumn (LC 318, 4.6mMx5.0mm). Chromatograms were detected by UV  
7  
8 detection at 210nm and 274nm (33).  
9

### 10 11 **Identification of the attached SST to AuNPs using sodium dodecyl sulfate**

#### 12 **polyacrylamide gel electrophoresis**

13  
14 The adsorbed SST to AuNPs was determined using SDS-PAGE as previously reported  
15 (34-35). In brief, 21 $\mu$ L of AuNPs-SST was mixed with 7 $\mu$ L modified SDS-PAGE  
16 sample buffer. Without heating, the samples were loaded in duplicates onto a 6% SDS-  
17 PAGE gel. Then, the normal gel running procedure was followed. Putamol was used to  
18 over fill the separating gel. Electrophoresis was run in a constant mode at 100mA using  
19 Pharmacia Biotech Electrophoresis Power Supply EPS (Bridge Path Scientific, 4841  
20 International Boulevard, Frederick, MD 21703). It was running on discontinuous buffer  
21 system. The running was also using separating gels (6%) and collecting gel (1.2mL  
22 acrylimide, 2mL collecting gel buffer, 5 $\mu$ L TEMED and 80 $\mu$ L APS 10%). 10 $\mu$ L of  
23 protein ladder of 19, 26, 34, 48, 85, or 117kDa were used as control protein. Gels were  
24 stained by Coomassie Brilliant Blue G-25 dispersion.

#### 43 **UV-VIS spectroscopy of AuNPs and AuNP-SST**

44 UV-VIS absorption spectra of the citrate-AuNPs, MUA-AuNPs and AuNPs decorated  
45 with SST were recorded using an Uvikon 941UV-VIS absorbance spectrophotometer  
46 (Kontron Instruments GmbH). It was taken five spectra of each gold colloid suspension  
47 in the range from 400to700nm. The absorbance measurements were made using 0.5cm  
48 path length quartz cuvettes. The SPR is clearly visible as a peak in the range between  
49 514 and 550nm.

### **Cellular uptake study**

HCC1806 cells were used to study the cellular uptake of SST-decorated AuNPs. HCC-1806 cells express all types of SSTRs. SSTRs expression was confirmed by Reverse Transcription Polymerase Chain Reaction (RT-PCR) (36). HCC-1806 cells were cultured in T-75 tissue culture flasks in RPMI 1640 supplemented with 10% FCS (37).

### **Cellular uptake study of AuNPs-SST using inductively coupled plasma-optical emission spectroscopy ICP-OES**

To determine quantitatively the number of AuNPs entered per cell, HCC-1806 cells were incubated for 1 hour at 37°C with 1mL of 100nM of citrate-AuNPs and AuNPs-SST. The incubation was performed in 1mL of serum-containing culture medium with serum free Leibowitz medium in T-75 tissue culture flasks. To displace the bound AuNPs-SST, the cells were incubated prior to the experiment for 20 minutes with 100µL of 1mM antagonist (cyn-164806). The AuNPs concentrations were determined in 96-well plate using an Uvikon 941UV-VIS absorbance spectrophotometer (Kontron Instruments GmbH) (38). To harvest cells, 2mL of trypsin-EDTA was added to the flask. The flasks were incubated at 37±0.5°C for 3 minutes to allow cell detachment. The cells were washed with DPBS two times, followed by centrifugation at 300×g (18±0.5°C) for 5 minutes in order to pellet the cells. The cells were transferred to a 5mL glass vials.

### **ICP-OES sample preparation and determination of AuNPs**

This technique is specifically used to determine the concentration of Au<sup>3+</sup> metals, minor and major concentrations as a previously reported (30, 39). Typically, 500µL of each sample containing AuNPs was mixed with 200µL of freshly prepared aqua regia

1  
2  
3  
4 then diluted to 5mL with Millipore water. The Au<sup>3+</sup> content of the digested cells was  
5  
6 determined using ICP-OES on a JY-70 PLUS (Jobin Yvon Instruments S.A.). The  
7  
8 plasma flow was 16mL/minute argon. Concentrations of 1, 10 and 100ppm were used  
9  
10 as a standard concentration of gold (III) chloride. The numbers of AuNPs per cell were  
11  
12 determined by ICP-OES (for details of calculation refer the Supporting Information).  
13  
14

### 15 16 **Statistical analysis**

17  
18 Cellular uptake study was subjected to statistical analysis using One-way analysis of  
19  
20 variance (ANOVA). Minitab® 16 Statistical Software with the Tukey's multiple  
21  
22 comparison was employed for comparing the formulations with each other. Statistically  
23  
24 significant differences were assumed when p<0.05.

## Results and discussion

### Preparation and characterization of AuNPs

Citrate coated AuNPs were synthesized as reported previously (30). During this synthesis, a color change was observed when tri-sodium citrate was added to  $\text{HAuCl}_4$  solution. The solution was initially of yellowish color. After the citrate was added, the color changed first to light blue, dark blue, then purple, dark purple, and finally red to purple in color (Figure 2).

#### Insert Figure 2 here

The obtained series of colour change indicated the formation of small and uniform citrate-AuNPs via the citrate-reduction method using a molar ratio of 3:1 tri-sodium citrate to  $\text{HAuCl}_4$ . Furthermore, the formulated citrate-AuNPs were uniform in particle size of  $19.3 \pm 0.5 \text{ nm}$  and had a negative surface charge of  $-43.4 \pm 0.5 \text{ mV}$  (Figure 3).

Size (hydrodynamic diameter), Polydispersity index (PDI) and zeta potential of particles are parameters that indicate the stability of nanoparticles(40-41). High PDI indicates the heterogeneity of the particle size in suspension. While smaller PDI values indicate the homogeneity of the particle size in suspension. It was reported that PDI lower than 0.2 is considered to be ideal hence, the particle size distribution falls within a narrow range of size (40, 42-45). The surface charge also plays an important role in the stability of the nanoparticles and the magnitude of zeta potential is indicative of the colloidal stability of the system (46).

In addition, the mean count rate and PDI were monitored as shown in (Figure 3). The high-count rate 185 kpcs, indicated that the concentration of nanoparticles was high

1  
2  
3  
4 enough for measurements. Furthermore, the PDI was very small 0.16, indicating that  
5  
6 the colloidal AuNPs were uniform and has a very narrow size distribution range.  
7  
8

9  
10 **Insert Figure 3 here**

11  
12 **Stabilization of the synthesized AuNPs using 11-MUA**

13  
14 A stronger stabilizing agent, 11-MUA, was used instead of citrate to achieve successful  
15  
16 coating of AuNPs with SST. 11-MUA is a thiol compound that binds strongly to gold  
17  
18 surfaces. Citrate-AuNPs were coated with 11-MUA at pH 11. The carboxyl group of  
19  
20 11-MUA is deprotonated at pH 11 and can stabilize the particle dispersion via  
21  
22 electrostatic repulsion (32). After coating of AuNPs with 11-MUA, the size increased  
23  
24 to  $23.5 \pm 0.05$  nm with a PDI of about 0.2 (Figure 4). After the purification of MUA-  
25  
26 AuNPs, the PDI decreased to a value of 0.1 indicating that the free 11-MUA was  
27  
28 removed from the colloidal solution, and MUA-AuNPs turned to a more stable and  
29  
30 more monodisperse colloidal solution.  
31  
32  
33

34  
35  
36 It was found that the zeta potential was highly negative  $-73.2 \pm 0.06$  mV for crude MUA-  
37  
38 AuNPs. After purification, the zeta potential increased to become less negative -  
39  
40  $65.3 \pm 0.1$  mV, but still high enough to stabilize the particles in an aqueous environment  
41  
42 as shown in (Figure 5). On the same time, this highly negative charge is ideal for an  
43  
44 adsorptive immobilization of SST.  
45  
46  
47

48  
49 **Insert Figures 4 and 5 here**

50  
51 **Influence of different ionic strength on the stability of MUA-AuNPs**

52  
53 Ionic strength is very important for the stability of colloidal nanoparticles (47). In  
54  
55 addition, ionic strength is considered one of the most important factors that influence  
56  
57  
58  
59  
60

1  
2  
3  
4 the adhesion of a molecule to nanoparticles surfaces (30). To determine the ideal ionic  
5  
6 strength, different concentrations of NaCl (10, 20 and 30mM) were tried for to choose  
7  
8 the probable conc. which stabilize the coating of MUA-AuNPs with SST.  
9  
10 Furthermore, the stability of the particles at different ionic strengths was determined by  
11  
12 monitoring the change in the particles size, zeta potential and PDI. A concentration of  
13  
14 10mM NaCl proved to be a suitable ionic strength for maintaining a small  
15  
16 hydrodynamic diameter and low PDI of MUA-AuNPs during the coating and  
17  
18 purification processes. On the other hand, MUA-AuNPs with 20mM and 30mM NaCl,  
19  
20 showed aggregation with undefined particle sizes. The PDI of MUA-AuNPs of 10mM  
21  
22 NaCl was  $0.2\pm 0.04$ . In contrast, the PDI for 20 and 30mM NaCl was  $0.34\pm 0.8$  and  
23  
24  $0.5\pm 0.3$ ; respectively as shown in (Figure 6) which indicated the beginning of particle  
25  
26 aggregation and instability. This could be attributed to the increase in PDI in these  
27  
28 higher molar concentrations. It was found that increasing the ionic strength led to a  
29  
30 decrease in the Debye length between the particles concomitant with particles  
31  
32 aggregation (48).  
33  
34  
35  
36  
37  
38  
39

40 Zeta potential analysis was performed for identification of the change in the surface  
41  
42 charge of MUA-AuNPs at different ionic strengths (Figure 7). The MUA-AuNPs  
43  
44 mixed with 100 $\mu$ L of 10mM NaCl had a high negative surface charge of  $-60.7\pm 2.1$   
45  
46 owing to the presence of carboxylate anions from 11-MUA. Increasing the ionic  
47  
48 strength to 20 and 30mM decreased the negative surface potential to a value of -  
49  
50  $20.6\pm 0.5$  and  $-19.7\pm 6.8$ mV; respectively, leading to the aggregation of the  
51  
52 nanoparticles as shown in (Figure 7). This was accompanied by a color change from  
53  
54 red to blue as depicted in (Figure 2). This interaction is most likely due to increased  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 Van der Waals forces (46, 49-51). From the above results, it was clear that AuNPs are  
5  
6 reasonably stable after 11-MUA coating and resist aggregation in the presence of up to  
7  
8 10mM NaCl.  
9

10  
11 **Insert Figures 6 and 7 here.**  
12

### 13 14 15 **Coating of MUA-AuNPs with SST** 16

17 The coating process of SST on MUA-AUNPs could be performed according to the  
18  
19 adsorption between oppositely charged groups. SST, which has a positive charge, was  
20  
21 adsorbed on a negatively charged MUA-AuNPs. Different concentrations of SST were  
22  
23 tried to choose the best and high-adsorbed amounts of SST. The amount of SST  
24  
25 adsorbed to AuNPs seemed to increase from 20nM to 200nM. The particle sizes  
26  
27 increased to  $21.7\pm 0.06$ ,  $22.4\pm 0.3$ ,  $23.5\pm 0.2$ ,  $25.05\pm 0.07$  and  $28.3\pm 0.4$  for different SST  
28  
29 concentrations of 20, 40, 60, 100 and 200nM; respectively with acceptable PDI as  
30  
31 shown in (Table 1). After purification, the nanoparticles were stable without  
32  
33 aggregation. However, particles coated with a concentration of 200nM SST showed  
34  
35 aggregates after six hours, indicating that they are not acceptable preparations for a  
36  
37 long-term stability. For that reason, the ideal SST concentration to be used for coating  
38  
39 was chosen to be 100nM because the formed particles were stable in size and did not  
40  
41 form aggregates.  
42  
43  
44  
45  
46  
47

48 **(Insert Table 1 here)**  
49

50 Therefore, zeta potential was measured to confirm the successful coating of AuNPs  
51  
52 with SST. Citrate-AuNPs had a zeta potential of  $-40.9\pm 4.9$ mV. After deposition of 11-  
53  
54 MUA, it became more negative  $-60.8\pm 2.65$ mV, indicating that citrate was replaced  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 with 11-MUA and the surface of gold coated carboxylic acid groups. Moreover, the  
5  
6 zeta potential of all the investigated particles was initially negative then, after coating  
7  
8 with different concentrations of 20-200nM SST, it became more and more positive.  
9  
10 Furthermore, AuNPs-SST at 60, 100 and 200nM showed a reversal of the zeta potential  
11  
12 values from negative to positive (16.9, 20.3 and 29.3mV; respectively, Table 1). Thus,  
13  
14 zeta potential study proved the successful loading of SST on the surface of MUA-  
15  
16 AuNPs.  
17  
18  
19

### 20 21 **The significance of 11-MUA for coating of SST-AuNPs**

22 Since the citrate-AuNPs have a negative surface charge and SST has a positive charge.  
23  
24 SST might be deposited on the surface of AuNPs without of 11-MUA as an  
25  
26 intermediate coating. To investigate this aspect, AuNPs were mixed with SST solution  
27  
28 directly. The results of this experiment showed that 11-MUA is essential for coating of  
29  
30 SST to AuNPs. Since, the absence of 11-MUA during the coating of citrate-AuNPs  
31  
32 with SST led to an aggregation of AuNPs. Accordingly, the deposition of SST on  
33  
34 MUA-AuNPs showed no aggregation even at higher concentration of SST about  
35  
36 100nM (Figure 8a). While citrate-AuNPs formed aggregates after all purification steps  
37  
38 even it was coated with 20nM of SST (Figure 8b).  
39  
40  
41  
42  
43  
44

45 **Insert Figure 8 a&b here**

46  
47 Hence, it was worthy to use 11-MUA for coating of SST to AuNPs, since it make the  
48  
49 AuNPs more stable and can adsorb easily SST. Furthermore, the aggregation observed  
50  
51 in citrate-AuNPs could be possibly attributed to the failure of SST to replace the citrate  
52  
53 anion on the surface of AuNPs which may formed as positive negative complex or  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 could be the disulfide bond of SST was reduced by citrate that make the particles  
5 aggregated.  
6  
7

### 8 9 **Dissociation of AuNPs-SST by sodium dodecyl sulphate (SDS)**

10 The effects of ionic surfactants like SDS on AuNPs-SST were studied using HPLC. At  
11 pH 7.0, anionic surfactants such as SDS induce peptide dissociation for AuNPs-SST.  
12 For this reason, SDS was used to confirm the adsorption of SST to AuNPs. Figure 9  
13 shows the chromatograms of SST and SST dissociated from AuNPs-SST. The  
14 dissociation of SST from AuNPs showed a single peak eluted at about 3.6 minutes. The  
15 chromatogram showed no degradation products. The SST dissociated from AuNPs was  
16 eluted earlier than the free SST, because it was less hydrophilic due to the presence of  
17 some traces of 11-MUA. Thus, confirmed the adsorption of SST to AuNPs, which then  
18 dissociated from the AuNPs with SDS.  
19  
20  
21

23  
24  
25  
26  
27  
28  
29  
30  
31

32  
33 **Insert Figure 9 here**  
34

35 SST adsorbed to the surface of AuNPs was also analyzed using SDS-PAGE. Figure 10  
36 shows the SDS-PAGE containing a single band for AuNPs-SST (lane 5) that does not  
37 move. This confirmed the attachment of SST to the AuNPs which hinder the peptide  
38 from moving in the applied electric field(52-53). On the other hand, the 100nM  
39 concentration of SST and citrate-AuNPs showed no bands (lane 3 and lane 4;  
40 respectively). However, increasing the concentration of SST to 100nM resulted in  
41 appearance of band (lane 2) which is also confirmed the attachment of SST to AuNPs.

### **UV-VIS spectroscopy of AuNPs and AuNPs decorated with SST**

The optical properties of AuNPs are highly dependent on the nanoparticle diameter. Smaller nanoparticles absorb light and have peaks near 520nm, while larger spheres exhibit increased scattering and have peaks shifted towards longer wavelengths (known as red-shif). Furthermore, larger spheres scatter more light because they have larger optical cross sections, and their albedo (a ratio of scattering to total extinction) increases with size. AuNPs are often used as bio-imaging tags in dark field microscopy techniques, where the scattering from individual nanoparticles with diameters larger than 40-50nm can be observed(54). The UV-VIS spectra of citrate-AuNPs, MUA-AuNPs and AuNPs-SST showed a small red shift in the surface Plasmon resonance peak. The shifts observed were of values of 5 and 4nm for MUA-AuNPs and AuNPs-SST; respectively as shown in (Figure 11). This could be possibly attributed to the deposition of 11-MUA and SST on AuNPs and increasing the nanoparticles size.

**Insert Figure 11 here**

### **Cellular uptake study**

To study the cellular uptake of AuNPs-SST, HCC-1806 cells were chosen as a model cell lines. HCC-1806 cells were incubated with citrate-AuNPs (as control nanoparticles) and AuNPs-SST for 1 hour in RPMI 1640 medium containing serum. HCC-1806 cells took up all types of AuNPs and the average amount of AuNPs per cell strongly depended on the type of the top layer. Since all kinds of AuNPs are of nearly similar sizes but possess different outer layers, this suggests that surface properties may strongly affect interactions with the cells. The number of AuNPs per cell was determined by ICP-OES. The initial concentration of AuNPs in the culture medium

1  
2  
3  
4 was 100nM for citrate-AuNPs, MUA-AuNPs and AuNPs-SST. AuNPs-SST were  
5  
6 internalized in significantly ( $p < 0.05$ ; ANOVA/Tukey) higher amounts (estimated  
7  
8 number,  $15393 \pm 656$  per cell) more than citrate-AuNPs and AuNPs-SST (estimated  
9  
10 number  $3779 \pm 758$  and  $8649 \pm 570$  per cell; respectively) in the presence of the  
11  
12 antagonist (cyn 154806) as shown in (Figure 12). However, the higher amounts of  
13  
14 antagonist up to 1mM displaced the nanoparticles from the receptor. Hence, it can be  
15  
16 concluded that the difference in the cellular uptake of AuNPs-SST is due to differences  
17  
18 in surface properties and not in the size of AuNPs. Nanoparticle interaction with cells  
19  
20 is an issue of importance for targeting of these particles to different cells. These results  
21  
22 On the one hand there counteract the evidence of unwanted interactions such that  
23  
24 particles enter cells with a non-specific way when they are exposed to colloids. SST as  
25  
26 SSTRs agonist could easily fit on the SSTRs which increase the internalization of  
27  
28 AuNPs, whilst blocking of these receptors by antagonist like cyn-154806 led to  
29  
30 internalization of AuNPs.

## Conclusions

Citrate-AuNPs were efficiently synthesized via the citrate-reduction method. They are uniform in size  $19.3 \pm 0.5 \text{ nm}$  and had a negative charge of  $-43.4 \pm 0.5 \text{ mV}$ . Moreover, AuNPs were stable, resist the aggregation and successfully coated with SST after binding with 11-MUA instead of citrate ions. All analytical tools used in our study e.g., DLS, SDS-PAGE and UV-VIS absorption spectra confirmed the attachment of SST to AuNPs. In addition, significantly ( $p < 0.05$ ; ANOVA/Tukey) higher amounts AuNPs-SST particles internalized per cell in HCC-1806 cell lines compared to citrate-AuNPs and AuNPs-SST in the presence of antagonists. Such internalization depends on the surface properties of the cells not on the size of particles as shown when the receptors were blocked by incorporation of antagonist. Finally, the proof of principle has been addressed and we will focusing our research in the future in the delivery of these novel AuNPs coated with SST to various tumor cells.

33 Figure 1: Schematic diagram for deposition of SST onto MUA-AuNPs. 10mM of NaCl used as isotonic  
34 solution. MUA-AuNPs was added drop-wise to 10 $\mu$ L of concentration of 100nM SST stirred for 30 minutes  
35 and purified by centrifugation at 15,700 $\times$ g for 15 minutes.  
36 254x190mm (72 x 72 DPI)

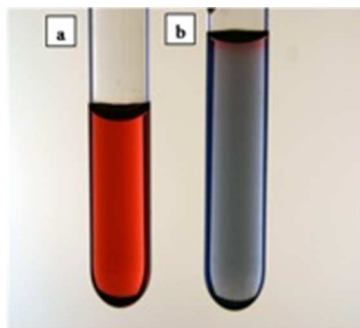

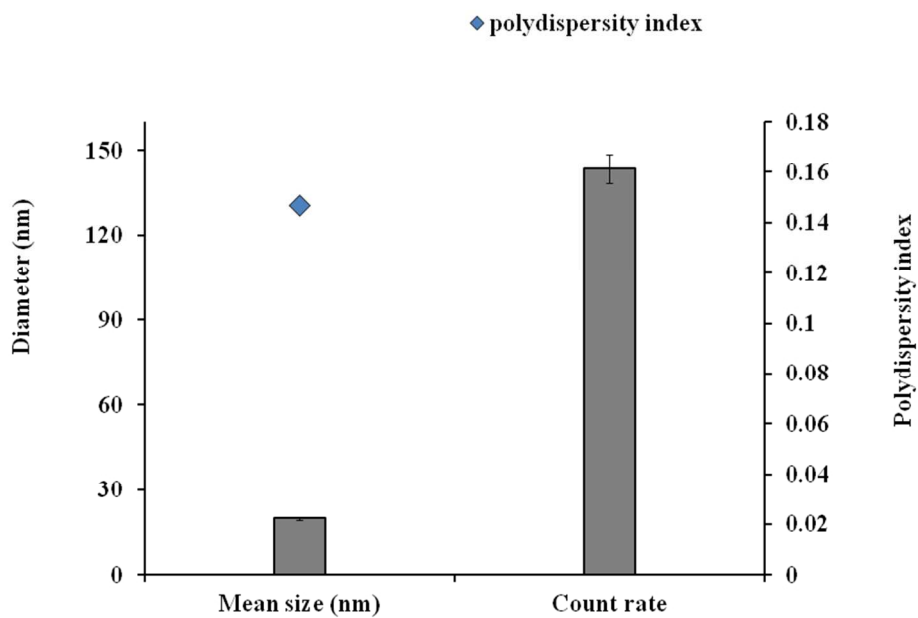

Figure 2: Image of a) monodispersed AuNPs with red to purple color, b) polydispersed aggregated AuNPs with a blue color.  
63x57mm (72 x 72 DPI)

Peer Review Only

32 Figure 3: Particle size distribution, count rate as well as the polydispersity index (black diamond) of citrate-  
33 AuNPs of 19nm using DLS.  
34 254x190mm (96 x 96 DPI)

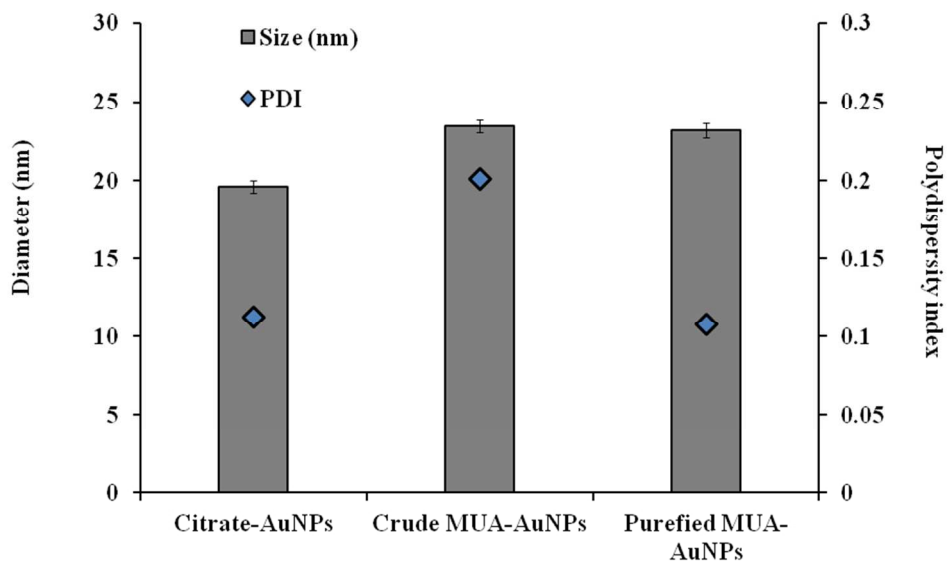

Figure 4: The hydrodynamic diameter as well as PDI of citrate-AuNPs, crude MUA-AuNPs and purified MUA-AuNPs.

254x190mm (96 x 96 DPI)

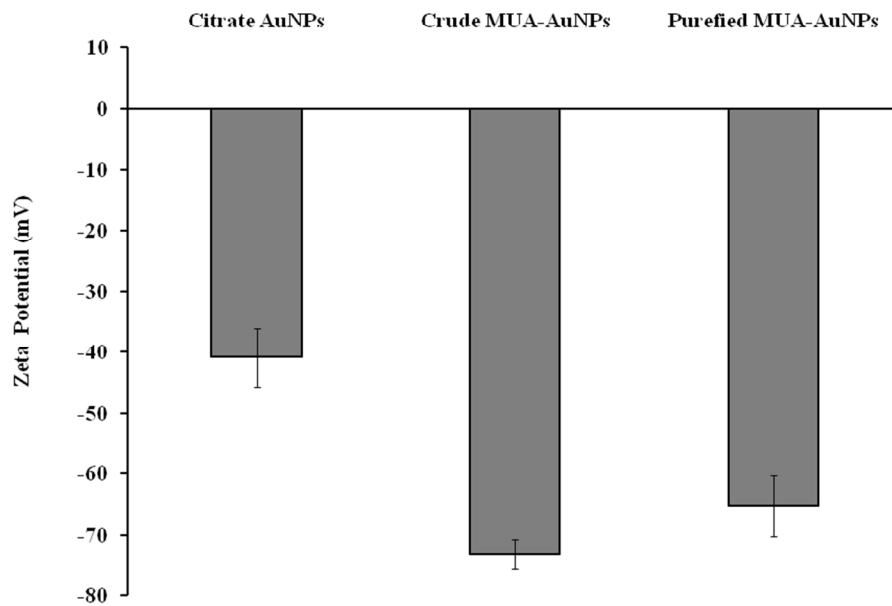

Figure 5: Zeta potential of citrate-AuNPs, crude MUA-AuNPs and purified MUA-AuNPs as a function of stability.

254x190mm (96 x 96 DPI)

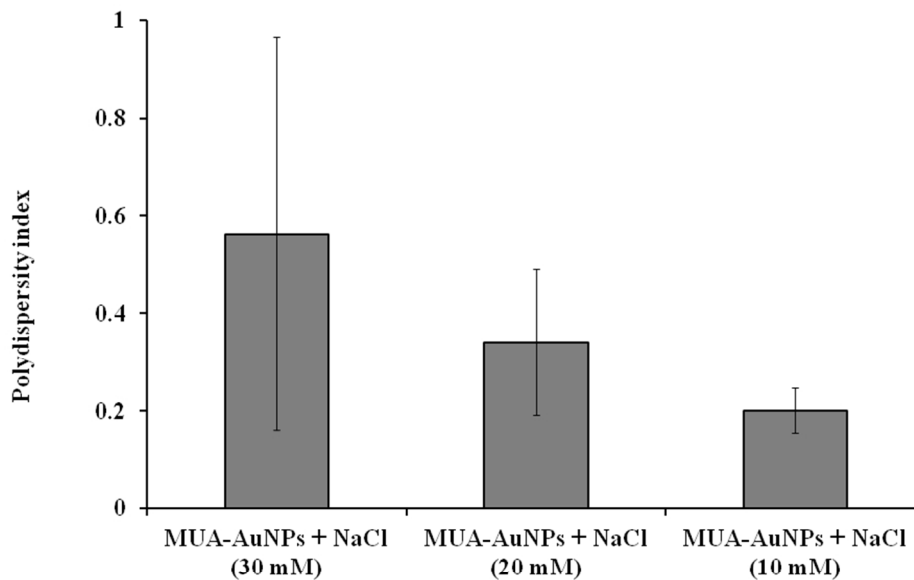

Figure 6: Influence of ionic strength on the polydispersity index of 11-MUA coated AuNPs. The PDI of MUA-AuNPs with 10 mM NaCl is satisfactory low. In contrast, the PDI with 20 and 30 mM NaCl were much higher, which indicate the beginning of aggregation.

254x190mm (96 x 96 DPI)

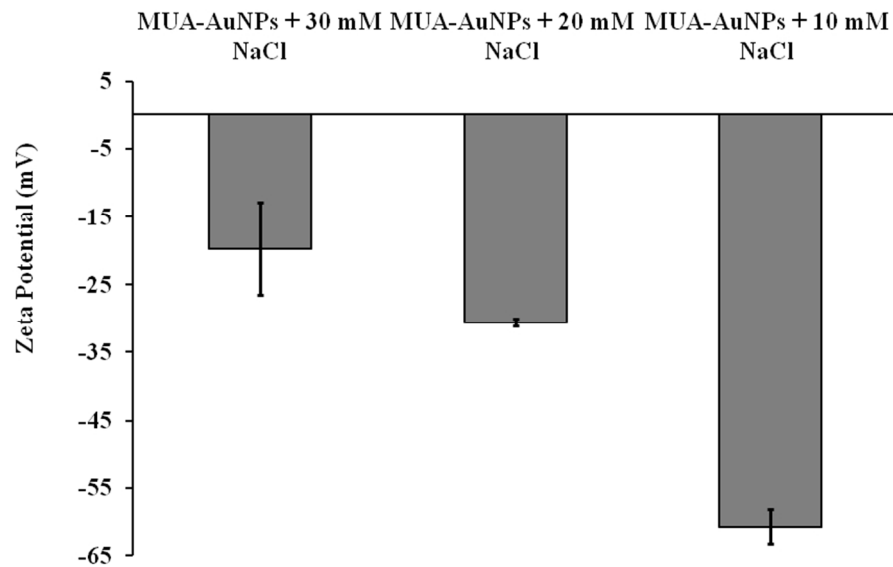

Figure 7: Zeta potential measurements of MUA-AuNPs at different ionic strength (10, 20 and 30)mM NaCl . The MUA-AuNPs mixed with 10mM NaCl had a high negative surface charge. Increasing the ionic strength to 20 and 30mM, decreased the negative surface potential, leading to aggregation of the nanoparticles. This was accompanied by a color change from red to blue.  
254x190mm (96 x 96 DPI)

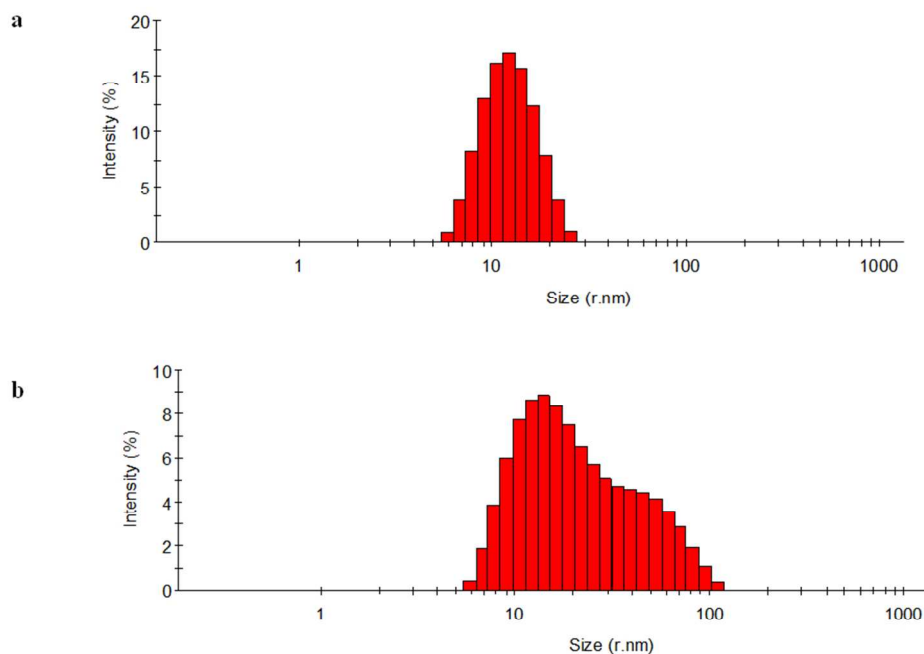

Figure 8: Particle size distribution of AuNPs measured using DLS. a). Coated with SST at concentration of 100nM after deposition on MUA-AuNPs using 10mM NaCl as polyelectrolyte. b). Coated directly with SST at concentration of 20nM after deposition directly on citrate-AuNPs without using 10mM NaCl as polyelectrolyte.  
254x190mm (96 x 96 DPI)

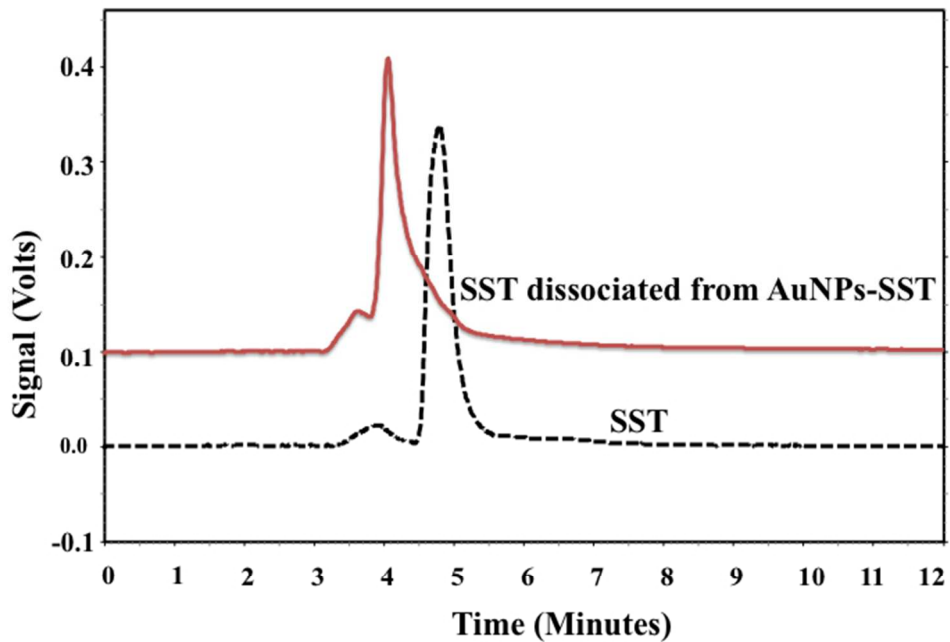

Figure 9: HPLC chromatograms of SST dissociated from AuNPs-SST using SDS.  
254x190mm (72 x 72 DPI)

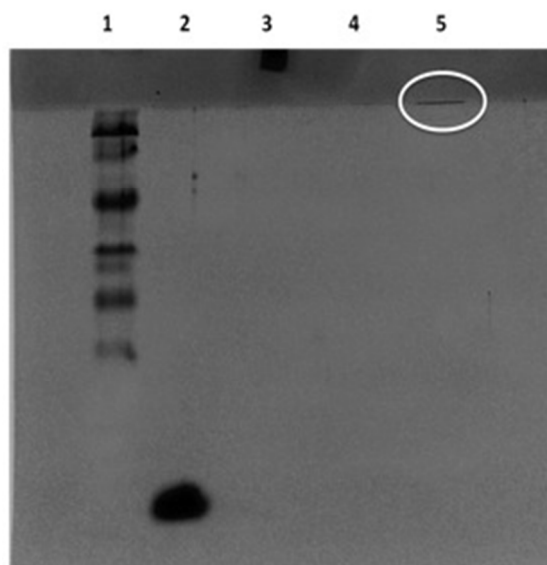

Figure 10: SDS-PAGE analysis for identification of the attachment of SST to AuNPs using 20% acrylamide, and protein ladder 19KDa. For identification of SST, a protein ladder was used (lane 1). High conc. of SST (10mM) (lane 2), 100nM SST (lane 3), citrate-AuNPs (lane 4) and 200nM AuNPs decorated with SST (lane 5).

97x101mm (72 x 72 DPI)

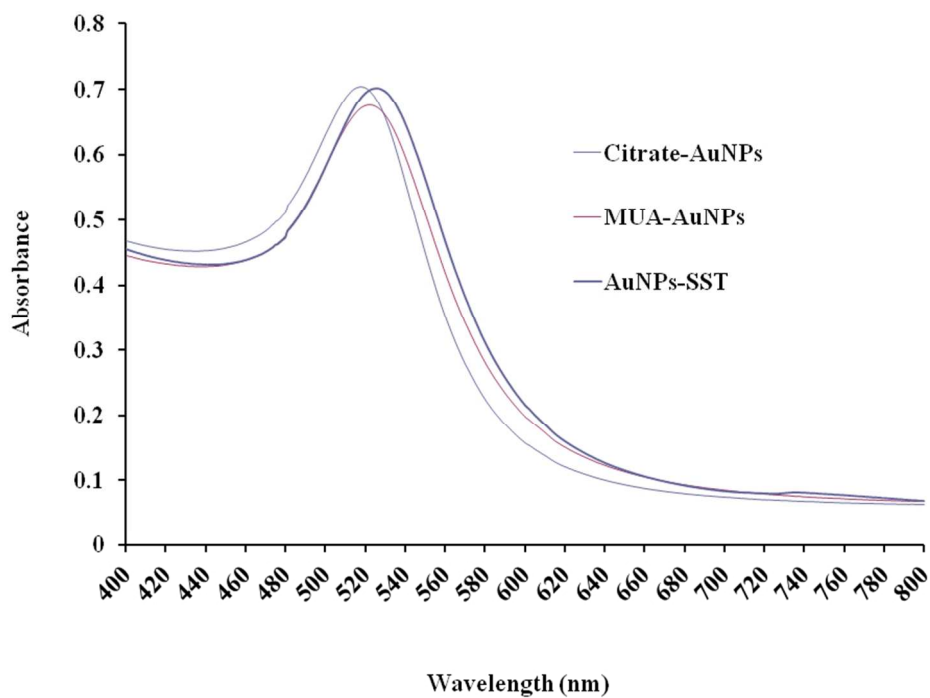

Figure 11: UV-VIS spectra of AuNPs, from top to bottom: citrate-AuNPs, purified AuNPs capped 11-MUA, and purified AuNPs decorated with SST.  
254x190mm (96 x 96 DPI)

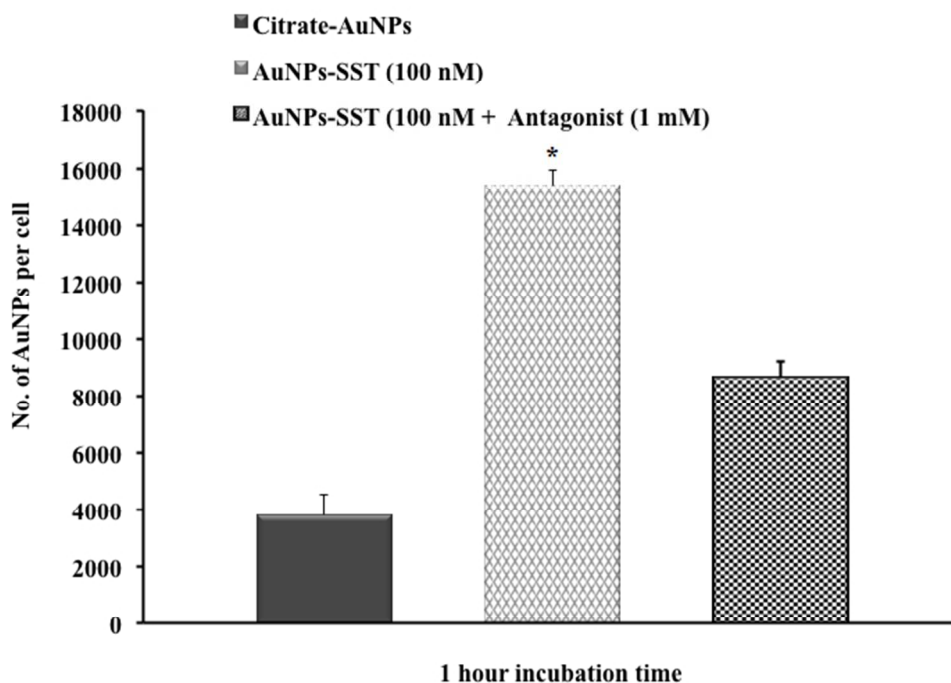

Figure 12: The cellular uptake of AuNPs as determined by ICP-OES and cell counting after 1 hour of incubation. The concentration of AuNPs in the culture medium was 100nM for citrate-AuNPs, and AuNPs-SST. \* Significantly different ( $p < 0.05$ ; ANOVA/Tukey) versus citrate-AuNPs and AuNPs-SST (100nM + antagonist (1m)).

190x142mm (96 x 96 DPI)

Table 1: Particle size by intensity (percentage), polydispersity index as well as zeta potential of AuNPs coated with different concentrations of SST.

Parameters	SST concentration (nM)	Size (nm)	PDI	zeta potential (mV)
Citrate-AuNPs	0	18.2±0.2	0.14	- 40.93±4.8
MUA-AuNPs	0	20.2±0.1	0.12	- 60.63±2.6
AuNPs-SST	20	21.7±0.1	0.2	- 46.8±2.6
AuNPs-SST	40	22.5±0.3	0.1	- 22.7±1.9
AuNPs-SST	60	23.5±0.2	0.2	16.9±2.9
AuNPs-SST	100	25.1±0.1	0.1	20.3±1.3
AuNPs-SST	200	28.3±0.4	0.2	29.3±1.3
