26 25B-NBOMe and 25C-NBOMe are potent 5-HT<sub>2A</sub> receptor agonists that have been associated with 27 inducing hallucinogenic effects in drug users and severe intoxications. This paper describes the 28 identification of their metabolites in rat and human urine by liquid chromatography (LC)-high 29 resolution (HR)-MS/MS, the comparison of metabolite formation in vitro and in vivo and in different 30 species, the general involvement of human cytochrome-P450 (CYP) isoenzymes on their metabolism 31 steps, and their detectability by standard urine screening approaches (SUSAs) using GC-MS, LC-32 MS<sup>n</sup>, or LC-HR-MS/MS. Both NBOMe derivatives were mainly metabolized by O-demethylation, 33 O,O-bis-demethylation, hydroxylation, and combinations as well as by glucuronidation and sulfation 34 of the main phase I metabolites. For 25B-NBOMe, 66 metabolites could be identified and 69 for 25C-35 NBOMe. After application of low doses of both substances to rats, they were detectable mainly via 36 their metabolites by both LC-based SUSAs. In case of acute intoxication, it was possible to detect 37 25B-NBOMe and its metabolites in an authentic human urine sample when using the GC-MS SUSA in addition to the LC-based SUSAs. Initial CYP activity screening revealed the involvement of 38 39 CYP1A2 and CYP3A4 in hydroxylation and CYP2C9 and CYP2C19 in O-demethylation. The 40 presented study demonstrated that 25B-NBOMe and 25C-NBOMe were extensively metabolized and 41 detectable by both LC-based SUSAs.

54 According to annual drug reports published by the European Monitoring Centre for Drugs and Drug 55 Addiction (EMCDDA) and United Nations Office on Drugs and Crime (UNODC) [1-4], the 56 availability and abuse of new psychoactive substances (NPS) increased during the last few years. 57 Besides synthetic cannabinoids, cathinones, opioids, and tryptamines, the group of phenethylamines 58 gained more importance in the last years [5]. Among others, the so-called 2C-type phenethylamines 59 have been a constant feature in the detection of NPS [6]. They were first described by Alexander 60 Shulgin in his book PIHKAL [7]. Like many phenethylamines, they have powerful psychoactive and 61 stimulating effects [7,8]. Although many of them have been scheduled, new and uncontrolled 62 alternatives have emerged. Structure-activity relationship studies revealed that derivatization of the 63 primary amine of the 2C partial structure with a 2-methoxybenzyl substituent significantly increased 64 the affinity toward the serotonin 5-HT<sub>2A</sub> receptor, thus, mediating potent hallucinogenic effects [9-65 12]. The resulting 2C derivatives, the so-called NBOMes (N-2-methoxybenzyl phenethylamines), 66 represent a new group of potent phenethylamine hallucinogens with high abuse potential. 2-(4-67 Bromo-2,5-dimethoxyphenyl)-N-[(2-methoxy¬phenyl)methyl]ethanamine (25B-NBOMe, 2C-B-68 2-(4-chloro-2,5-dimethoxyphenyl)-*N*-[(2-methoxy¬phenyl)methyl]ethanamine (25C-NBOMe), 69 2C-C-NBOMe), 2-(4-iodo-2,5-dimethoxyphenyl)-N-[(2-NBOMe, and 70 methoxyphenyl)methyl]ethanamine, 25I-NBOMe, 2C-I-NBOMe) are among the most prevalent 71 NBOMes. They are consumed depending on desired effects in reported dosages between 200-1,000 72 µg, administered orally, sublingually, bucally or insufflated as powder or in solution as nose spray 73 [8,13-20]. In recent years, NBOMe consumption was described in the context of acute and severe 74 intoxications and fatalities [8,14-18,21,22]. In some cases, an unintentional intake of NBOMes, sold 75 as LSD or 2Cs, were found to be responsible for adverse events [8,15,19,22]. However, 25B-NBOMe 76 has also been employed in positron emission tomography (PET) in human volunteers to assess 77 binding of this ligand in distinct brain areas and at non-psychoactive dosage levels [23,24].

78 Due to high receptor affinity and functional activity as full agonists, comparatively low doses, 79 comparable to LSD, are needed to induce psychoactive effects. Consequently, the resulting low blood 80 plasma or urine concentrations can make it challenging to identify and characterize the intake of 81 NBOMes. In urine, the concentration of compounds is generally higher than in blood, but in many 82 cases, metabolites rather than the parent compounds are the targets. Therefore, metabolism studies 83 are needed for the development of urine screening approaches. The comprehensive metabolism study 84 for 25I-NBOMe revealed that it was extensively metabolized and that the parent compound was 85 found in urine only in small amounts [25].

86 Recently, Wohlfarth et al. [26] described the metabolism of 25C-NBOMe and 25I-NBOMe in mice 87 and human urine as well as in human hepatocytes, and the reported results were consistent with 88 previously published human and rat data for 25I-NBOMe [25]. For 25B-NBOMe, only limited data 89 on its biotransformation are available [27,28], and for both compounds, no comprehensive data 90 appear to be available on their detectability. Therefore, the aims of the present study were to 91 investigate the metabolism of 25B-NBOMe and 25C-NBOMe in rats and humans with LC-HR-92 MS/MS, to compare the results with in vitro and in vivo data and between different species, and to 93 investigate their detectability by the authors' standard urine screening approaches (SUSA) by GC-94 MS, LC-MS<sup>n</sup>, and LC-HR-MS/MS, respectively.

95

97

98 2.1. Chemicals and reagents

99

25B-NBOMe hydrochloride and 25C-NBOMe hydrochloride were purchased by LGC Standards
(Wesel, Germany). Isolute HCX cartridges (130 mg, 3 mL) were obtained from Biotage (Uppsala,
Sweden), isocitrate and isocitrate dehydrogenase from Sigma (Taufkirchen, Germany), NADP<sup>+</sup> from
Biomol (Hamburg, Germany), acetonitrile (LC-MS grade), ammonium formate (analytical grade),

<sup>96 2.</sup> Experimental

104 formic acid (LC-MS grade), methanol (LC-MS grade), mixture (100,000 Fishman units/mL) of 105 glucuronidase (EC No. 3.2.1.31) and arylsulfatase (EC No. 3.1.6.1) from Helix Pomatia, and all other 106 chemicals and reagents (analytical grade) from VWR (Darmstadt, Germany). The baculovirus-107 infected insect cell microsomes (Supersomes) containing 1 nmol/mL of human cDNA-expressed 108 CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1 (2 nmol/mL), 109 CYP3A4, or CYP3A5 (2 nmol/mL) were obtained from Corning (Amsterdam, The Netherlands). After delivery, the CYPs were thawed at 37°C, aliquoted, snap-frozen in liquid nitrogen, and stored at 110 111 -80°C until use.

112

113 *2.2. Urine samples* 

114

115 According to an established study design [29], the investigations were performed using rat urine 116 samples from male Wistar rats (Charles River, Sulzfeld, Germany) for toxicological diagnostic 117 reasons according to German law. Both compounds were administered in an aqueous suspension by 118 gastric intubation of a single 10 mg/kg body weight (BW) dose for identification of the metabolites 119 and of 0.1 mg/kg BW for screening (dose calculated based on common single dose reported in trip 120 reports (https://www.erowid.org) and scaled by dose-by-factor approach from man to rat according to 121 Sharma and McNeill [30]), respectively. The rats were housed in metabolism cages for 24 h, having 122 water ad libitum. Urine was collected separately from feces over a 24 h period. Blank urine samples 123 were collected before drug administration to verify that the samples were free of interfering 124 compounds. The samples were directly analyzed and then stored at -20°C.

In addition, for 25B-NBOMe, an authentic ante mortem human urine sample after unintentional intake of an unknown dose of 25B-NBOMe (declared as 2C-B) submitted to the authors' laboratory for toxicological diagnostics was also analyzed.

128

129 2.3. Sample preparation

155 CYP3A4, or CYP3A5 for 30 min. Besides enzymes and substrates, the incubation mixtures (final

volume, 50  $\mu$ L) contained 90 mM phosphate buffer (pH 7.4), 5 mM Mg<sup>2+</sup>, 5 mM isocitrate, 1.2 mM NADP<sup>+</sup>, 0.5 U/mL isocitrate dehydrogenase, and 200 U/mL superoxide dismutase. For incubations with CYP2A6 and CYP2C9, phosphate buffer was replaced with 45 mM or 90 mM Tris buffer, respectively, according to the Gentest manual. Reactions were initiated by addition of the CYP enzymes and stopped with 50  $\mu$ L of ice-cold acetonitrile. The solution was centrifuged for 2 min at 14,000 rpm; 70  $\mu$ L of the supernatant phase were transferred to an autosampler vial and 5  $\mu$ L injected onto the LC-HR-MS/MS system.

163

164 2.5. LC-HR-MS/MS instrumentation for identification of phase I and II metabolites and CYP initial
165 screening

166

According to a published procedure [32], the extracts were analyzed using a ThermoFisher Scientific (TF, Dreieich, Germany) Dionex UltiMate 3000 RS pump consisting of a degasser, a quaternary pump, and an UltiMate autosampler, coupled to a TF Q-Exactive Plus system equipped with a heated electrospray ionization (HESI)-II source. The instrument was used in positive or in negative ionization mode. Mass calibration was performed prior to analysis according to the manufacturer's recommendations using external mass calibration.

Gradient elution was run on a TF Accucore PhenylHexyl column (100 mm x 2.1 mm, 2.6  $\mu$ m). The mobile phases consisted of 2 mM aqueous ammonium formate containing formic acid (0.1%, *v/v*) and acetonitrile (1%, *v/v*) (pH 3, eluent A) and 2 mM ammonium formate solution with acetonitrile:methanol (50:50, *v/v*) containing formic acid (0.1%, *v/v*) and water (1%, *v/v*) (eluent B). The gradient and flow rate were programmed as follows: 0-1 min hold 99% A, 1-16 min 95% A to 5% A, 16-18 min hold 5% A, and 18-20 min hold 99% A, constantly at 500  $\mu$ L/min. The HESI-II source conditions were as follows: sheath gas, 60 arbitrary units (AU); auxiliary gas, 10

1/9 The filesi-fi source conditions were as follows. sheath gas, of arounary units (AO), auxiliary gas, fo

180 AU; spray voltage, 3.00 (positive polarity) and -4.00 kV (negative polarity); heater temperature,

181 320°C; ion transfer capillary temperature, 320°C; and S-lens RF level, 60.0. Mass spectrometry was

182 performed in positive and negative polarity mode using full scan (FS) data and a subsequent data 183 dependent acquisition (DDA) mode with an inclusion list on the masses of interest (phase I or phase 184 II metabolites). Additionally, DDA runs without inclusion list (positive and negative mode) were 185 performed to detect unexpected metabolites. 186 The settings for FS data acquisition were as follows: resolution, 35,000; microscans, 1; automatic 187 gain control (AGC) target, 1e6; maximum injection time (IT), 120 ms; and scan range, m/z 100–700. 188 The settings for the DDA mode with and without an inclusion list were as follows: resolution, 17,500; 189 microscans 1, AGC target, 2e5; maximum IT, 250 ms; isolation window, 1.0 m/z, HCD with stepped 190 normalized collision energy (NCE), 17.5, 35, and 52.5%; spectrum data type, profile; and underfill 191 ratio, 0.5%. For the run without inclusion list, the five most intense precursor ions were transferred to 192 an exclusion list for 1 s (dynamic exclusion). 193 For analyzing the initial CYP activity screening, the MS settings and the mobile phases as well as the 194 gradient and flow rate were the same with the same inclusion list as for identification of phase I 195 metabolites. 196

```
197 2.6. Standard urine screening procedures (SUSAs)
```

198

199 The SUSAs were performed as described in the following references: GC-MS SUSA [33,34], LC-

200 MS<sup>n</sup> SUSA [25,35], and LC-HR-MS/MS SUSA [25,36].

201

202 **3. Results and discussion** 

203

204 3.1. Identification of metabolites

3.1.1. Identification of 25B-NBOMe and 25C-NBOMe and their phase I metabolites via HR-MS/MS
fragmentation

208 The HR-MS/MS fragmentation patterns and metabolite formation of 25B-NBOMe and 25C-209 NBOMe were similar to those described for 25I-NBOMe [25]. Briefly, and for discussion purposes, viewed 210 the molecules were as two distinct parts, i.e. the 4-halogenated 2.5-211 dimethoxyphenethylamine (2C) part and the N-(2-methoxybenzyl) (NBOMe) part. Due to the high 212 number of metabolites, the fragmentation patterns could not be discussed in detail for all metabolites 213 and only the typical fragment ions used for identification will be discussed.

214 In general, for both compounds and their metabolites, the precursor masses and the most abundant 215 fragment ions formed from unmodified or modified NBOMe parts were used to identify the 216 corresponding metabolites. As expected, the fragment ions formed by the NBOMe part were identical 217 for 25B-NBOMe and 25C-NBOMe. To confirm the predicted chemical structure of the metabolites, 218 the corresponding 2C fragment ions (Table S1 in the electronic supplementary data for 25B-NBOMe 219 and Table S2 for 25C-NBOMe) were used. For the N-dealkylated metabolites, no fragment ions of 220 the NBOMe part could be detected, but characteristic 2C fragmentation patterns for the bromo and 221 chloro analogues (Tables S1 and S2). The precursor masses (PM) are given with the calculated exact 222 masses.

223 25B-NBOMe (B1; PM at m/z 380.0856, M+H<sup>+</sup>) showed a fragmentation pattern characteristic also 224 for most of the detected metabolites. The most abundant fragment ion of m/z 121.0653 represented 225 the cleavage of the NBOMe moiety, followed by the loss of the methoxy group (-30.0105 u) 226 producing the tropylium ion of m/z 91.0548. The fragment ions representing the 2C part showed low 227 abundances of at least 1 % (Table S1). The fragment ion of m/z 258.0124 representing the 2C-B 228 iminium ion resulted from benzyl cleavage. A loss of NH (- 15.0109 u) formed the fragment ion of 229 m/z 243.0021 followed by a loss of a methyl radical (- 15.0235 u) of one of the two methoxy groups in 230 the 2C part resulting in fragment ion of m/z 227.9786. For the MS<sup>2</sup> spectrum of 25I-NBOMe, a 231 rearrangement was described in the literature [25]. In the parent spectrum of 25B-NBOMe, one 232 fragment ion could also be formed by the same rearrangement. The fragment ion of m/z 363.0596 233 resulted from a loss of ammonia (-17.0263 u) and appeared consistent with the postulated

rearrangement reaction. Few MS<sup>2</sup> spectra of metabolites also showed possible rearranged fragment

235 ions.

236 The fragmentation patterns of 25C-NBOMe (C1; PM at m/z 336.1361, M+H<sup>+</sup>) corresponded to those 237 of 25B-NBOMe and 25I-NBOMe. Similarly, the most abundant fragment ions in MS<sup>2</sup> were formed 238 by cleavage of the NBOMe moiety producing fragment ions of m/z 91.0548 and 121.0653. Also, the 239 fragment ions representing the 2C part showed a lower abundance of about 1 % (Table S2). The 240 fragment ions of m/z 214.0629, m/z 199.0526, and m/z 184.0291 represented the 2C-C iminium ion, 241 the subsequent loss of NH (- 15.0109 u), and the loss of a methyl radical (- 15.0235 u) of one of the 242 two methoxy groups, respectively. In the spectrum of 25C-NBOMe, no fragment ions indicating the 243 rearrangement were detected, possibly due to low relative abundance. However, in the MS<sup>2</sup> spectra of 244 some 25C-NBOMe metabolites (e.g. O-demethyl metabolite isomers 1 and 2, C16 and C17), some 245 rearranged fragment ions could also be detected. Overall, 35 phase I metabolites could be detected for 246 25B-NBOMe in urine and 36 for 25C-NBOMe, respectively. All phase I metabolites are listed in 247 Tables S1 and S2 in the electronic supplementary data.

For metabolite identification based on the MS<sup>2</sup> spectra, in most cases the representative fragment ion 248 249 for the NBOMe part was used. Unmodified NBOMe parts led to a fragment ion of m/z 121.0653. The 250 presence of this fragment ion led to the suggestion that the expected modification took place at the 2C 251 part based on the predicted precursor mass for the metabolite. An unchanged fragment ion of m/z252 121.0653 could be seen for the parent compounds (B1 and C1) as well as for mono- and bis-253 demethylated (B13, B14, B8 and C16, C17, C10), mono-hydroxylated (B29, B32 and C31, C32), bishydroxylated (B35), combined mono-demethylated with mono-hydroxylated (B22), dehydrogenated 254 255 (B20 and C24), dehydrogenated combined with mono-demethylated (B12 and C13), and mono-256 hydroxylated (B27 and C30) metabolites. On the other hand, the fragment ion of m/z 137.0603 257 represented mono-hydroxylation at the NBOMe part (B16, B23, B28, B30, B31 and C19, C25, C27, 258 C33, C35). At the NBOMe moiety, bis-hydroxylation led to the fragment ion of m/z 153.0552 (B33, 259 B34 and C34, C36) and O-demethylation to fragment ion of m/z 107.0497 (B7, B9, B10, B11, B15,

B19, B21 and C8, C9, C11, C12, C14, C18, C21, C23, C26). The fragment ion of m/z 107.0497 260 261 could also be found for the NBOMe mono-hydroxylated (B16, B23, B28, B31 and C19, C25, C27, C33) or NBOMe bis-hydroxylated (B34 and C34, C35, C36) metabolites, but consistently in 262 263 combination with the fragment ions of m/z 137.0603 or m/z 153.0552 as mentioned above. Therefore, 264 the absence of the fragment ions of m/z 137.0603 and 153.0552 indicated O-demethylation at the 265 NBOMe part. O-Demethylation combined with mono-hydroxylation led to fragment ion of m/z266 123.0446 (B17, B18, B24, B25 and C20, C22, C28, C29). As mentioned above, all N-267 demethoxybenzyl metabolites were identified based on the 2C part fragmentation patterns (B2-B6 268 and C2–C7).

269 In summary, the fragmentation patterns of both NBOMes corresponded to those of 25I-NBOMe. 270 Some compound-related characteristics were found for the bromo and chloro analogues as already 271 described for 25I-NBOMe. All metabolites, which were O-demethylated at the NBOMe part (m/z272 107.0497), showed higher abundances for fragment ions representing the 2C part probably due to a 273 hydrogen bond between the nitrogen and the hydroxy group resulting from O-demethylation at the 274 NBOMe part [25]. In addition, for these metabolites, the corresponding 2C fragment ion carrying the 275 nitrogen was represented by the 2C primary amine instead of the 2C iminium ion found for the parent 276 compounds or metabolites, which were not O-demethylated at the NBOMe part.

277 It was not possible in this study to identify the demethylated position of the methoxy group (2'- or 5'-278 position) or the position at which the NBOMe part was hydroxylated. Nevertheless, Wohlfarth et al. 279 [26] synthesized six potential 25C-NBOMe metabolites (2'- and 5'-O-demethyl-25C-NBOMe and 3-280 /4-/5- and 6-hydroxy-25C-NBOMe) to confirm the exact position of the metabolic reaction. They 281 observed that both in vivo samples (mouse and human urine) showed prevalence for O-demethylation 282 at the 5'-position. Furthermore, they observed that the most intense signal for a mono-hydroxylated 283 metabolite was detected for 5-hydroxy-25C-NBOMe in human urine as well as in mouse urine. In 284 general, Wohlfarth et al. described the same main metabolic steps compared to the present study and 285 25I-NBOMe [25]. In accordance, Leth-Petersen et al. [28] described that the main metabolic step
286 of 25B-NBOMe was also the 5'-O-demethylation in humans and pigs.

287

3.1.2. Identification of 25B-NBOMe and 25C-NBOMe and their phase I metabolites via HR-MS/MS
fragmentation

290

The phase II metabolite formation and fragmentation patterns were very similar for both compounds and comparable with those described for 25I-NBOMe. For both compounds, the precursor masses and the most abundant fragment ions formed from unmodified or modified NBOMe part were used to identify the corresponding phase II metabolites. 2C fragment ions were used to confirm the predicted metabolites.

Overall, 31 phase II metabolites could be identified for 25B-NBOMe and 33 for 25C-NBOMe. A list of all phase II metabolites is given in Tables S3 and S4 in the electronic supplementary data. All glucuronides eliminated glucuronic acid (- 176.0321 u) and all sulfates sulfuric acid (- 79.9568 u). Thus, the rest of the spectra of phase II conjugates was in accordance with the spectrum of the corresponding phase I metabolite. Also, for some phase II metabolites, fragment ions formed by conjugated partial structures could be used to elucidate the position of the conjugation.

302 As already described for 2C derivatives [37] and 25I-NBOMe the metabolites formed after N-303 demethoxybenzylation could further be conjugated by acetylation, glucuronidation, sulfation, or even 304 combinations of them. Furthermore, in accordance to 25I-NBOMe, an O,O-bis-demethylation of the 305 2C part led to a hydroquinone partial structure, which could further be conjugated with glutathione 306 (GSH). The degradation products of GSH conjugated metabolites could be found for both 307 compounds. Also the described conjugation catalyzed by catechol-O-methyl-transferase (COMT) 308 could be found for both NBOMes forming O-methyl metabolites (B33ME and C24ME, C36ME), 309 after bis-hydroxylation at the NBOMe part (m/z 167.0708) producing a catecholic partial structure.

313 For identification of the CYPs catalyzing the initial metabolic steps, the ten most abundant human 314 hepatic CYPs were incubated under conditions allowing a statement on the general involvement of a 315 particular CYP enzyme. It should be kept in mind that these qualitative data did not reflect a 316 quantitative contribution of a CYP to the hepatic clearance that would require the collection of 317 enzyme kinetic data [38], which was beyond the scope of this study. As summarized in Tables 1 and 318 2, CYP2C9 and CYP2C219 were involved in O-demethylation for both, 25B-NBOMe and 25C-NBOMe, respectively, CYP1A2 and CYP3A4 in hydroxylation, and CYP3A4 in N-319 320 demethoxybenzylation.

321

#### 322 *3.3. Proposed metabolic pathways*

323

According to the 25B-NBOMe metabolites identified in human and rat urine after cleavage of conjugates and 25C-NBOMe metabolites identified in rat urine after cleavage of conjugates (Tables S1 and S2), the following metabolic pathways, depicted in Figs. 1 and 2, could be proposed.

As expected, both compounds underwent the same main metabolic steps. *O*-Demethylation led to the most abundant peaks in human and rat urine followed by *O*-bis-demethylation and /or by *O*demethylation plus hydroxylation. *N*-Demethoxybenzylation led to only small peaks in both species. However, the relative abundance of the different metabolites varied between the species, but it should also be kept in mind that the rat urines were pooled over 24 h and the human urine was collected at an unknown time after administration of an unknown dose. Finally, the relation of the metabolites may vary over the time of excretion.

For both derivatives, the following phase I pathways could be found: mono-demethylation (B13–B15 and C16–C18), bis-demethylation (B8–B10 and C10–C12), tris-demethylation (B7 and C8) of the methoxy groups, mono- and bis-hydroxylation (B29–B32, B34, B35, and C31–C33, C35, C36), *N*- 337 demethoxybenzylation (B6 and C5), and combinations of mono-hydroxylation with mono-

demethylation (B22–B25 and C26–C29), and bis-demethylation (B16–B19 and C19–C23) as well as bis-hydroxylation with mono-demethylation (B33 and C34), and *N*-demethoxybenzylation with mono-demethylation (B3, B4 and C2, C3) followed by oxidative deamination (B2) and oxidation to the corresponding carboxylic acid (B5 and C4). In addition, for 25C-NBOMe also *N*demethoxybenzylation with mono-hydroxylation (C7), and oxidation forming an amide structure (C6) could be predicted. Also, dehydro metabolites (B20 and C24) were found for both compounds. The presence of this metabolic step was already described for 25I-NBOMe [25].

345 Nielsen et al. [39] described dehydrogenation as a CYP-catalyzed reaction. The resulting double 346 bond was located at the 2C moiety and not between the nitrogen and the α-carbon of the 2C moiety as 347 confirmed with reference standard of the 25I-NBOMe imine. These compounds could further be 348 metabolized by mono-demethylation (B11, B12 and C13-C15), bis-demethylation (C9), 349 hydroxylation (B26-B28 and C30), and combination of mono-demethylation and hydroxylation 350 (B21 and C25). However, the possibility could not be excluded that the dehydro compound could 351 also be formed by artificial dehydration of the corresponding hydroxy metabolite. If hydroxylation 352 took place at the  $\alpha$ -position to the nitrogen forming an unstable hemiaminal, then this metabolite 353 could further eliminate water under the ESI conditions described above. In summary, the metabolic 354 pathways for 25B-NBOMe and 25C-NBOMe corresponded to those described for 25I-NBOMe, i.e. 355 showing the same main phase I metabolism reactions.

The following phase II pathways could be proposed for humans and/or rats as given in Tables S3 and S4 and Figs. 1 and 2: sulfation (S) glucuronidation (G) and/or of the *O*-demethyl metabolites (B13/14S, B15S, B13G–B15G and C16/17S, C18S, C16G–C18G), of the *O*,*O*-bis-demethyl metabolites (B8S, B9/10S, B8G, B9/10G and C10S–C12S, C10G–C12G), of *O*,*O*,*O*-tris-demethyl metabolite (B7S, B7G and C8S, C8G), of the *O*-demethyl-hydroxy metabolites (B22S, B24/25S, B22G, B23, B24/25G and C22S, C27S, C28/29S), of the *O*,*O*-bis-demethyl-hydroxy metabolites (B16S, B17/18S, B16G, B19G and C20S, C19G–C22G), and of the hydroxy metabolites (B30G, 363 B31G and C31/32G, C33G). Glutathione (GSH) conjugation could be proposed for the O,O-bis-364 demethyl metabolite isomer 1 (B8-GSH-1, B8-GSH-2 and C10-GSH-1, C10-GSH-2), N-acetylation 365 (AC) for the N-demethoxybenzyl-O-demethyl metabolites (B3, B4 and C2, C3) followed by further 366 sulfation and/or glucuronidation (B3AC+S, B4AC+S, B3/4AC+G and C3/4AC+S, C2/3AC+G), and 367 O-methylation (ME) of the bis-hydroxy metabolite (C36ME) and the O-demethyl-bis-hydroxy 368 metabolites (B33ME and C34ME). In summary, all phase II pathways could be proposed for both 369 species except for glutathione conjugation, which was observed only in rats after administration of 370 the high dose.

371

#### 372 *3.4. Comparison of metabolite formation in vitro and in vivo and in different species*

373

374 In contrast to the development of new therapeutics drug, pharmacokinetic data are not routinely 375 collected for NPS before emergence on the market. For ethical reasons, controlled human studies are 376 not possible. Therefore, animal studies under controlled conditions are common in combination with 377 human in vivo assays as described e.g. in refs. [25,26]. Both data can be confirmed by authentic 378 human samples of e.g. intoxication cases. For development of urine screening approaches, it is 379 important to know the possible target. Thus, any metabolites identified first in animal urine can 380 become the main target in human urine considering e.g. inter-species and/or genetic variations in 381 drug metabolism and transport. For this reason, Tables 3 and 4 list the phase I and II metabolites 382 identified in this study compared to those detected in human liver microsomes (HLM) incubation, 383 porcine liver microsomes (PLM) incubation, mouse urine (MU), authentic human urines (HU), or 384 human hepatocyte (HP) incubation. Differences could be explained by species differences, higher 385 doses, and/or different sampling time after administration.

386

387 *3.4.1. 25B-NBOMe* 

389 Boumrah et al. [27] described 21 phase I and II metabolites of 25B-NBOMe identified only in vitro 390 after incubation with HLM and cofactors for CYPs and glucuronyl transferases. Leth-Petersen et al. 391 [28] compared formation of phase I metabolites in HLM and PLM incubations. In the present study, 392 35 phase I and 31 phase II metabolites have been identified in human and rat urine. According to 393 Table 3, in both urine samples, various metabolites could be identified not described by Boumrah et 394 al. or Leth-Petersen et al. Most of them were isomers of metabolites formed by combined metabolic 395 reactions such as mono- and bis-O-demethylation with hydroxylation or O-demethylation with N-396 dealkylation. Species differences occurred for the hydroxylation step because rats seemed to prefer 397 hydroxylation at the 2C part whereas human biotransformation might result in preferential 398 hydroxylation at the NBOMe part. Concerning phase II metabolism, Boumrah et al. investigated only 399 the glucuronide formation. In the present study, sulfation, N-acetylation, and O-methylation were 400 found in rat and human urine as further reactions. In addition, rats showed GSH conjugation and 401 combinations of N-acetylation with sulfation or glucuronidation. In contrast, the N-glucuronide of the 402 parent compound detected in HLM could not be found in the human or rat urine.

403

404 *3.4.2. 25C-NBOMe* 

405

406 Table 4 summarizes the data obtained in rat urine and those in human hepatocytes and urines of 407 humans and mice [26]. Concerning phase I metabolism, most metabolites were common for all 408 species while the highest number was found in the rat urine probably due to the high dosage, urine 409 collection time, sample preparations, and/or chromatographic separation. Some metabolites were 410 only detected in rat urine such as the combined N-dealkylated and O-demethylated metabolites or 411 various isomers of O,O-bis-demethyl-hydroxy metabolites. Wohlfarth et al. [26] described N-412 oxidation and carbonylation in the hepatocyte incubation although it was not clear why this could not 413 be found in their human and mice urine. As already described for 25B-NBOMe, rats seemed to 414 preferentially hydroxylated at the 2C part and humans at the NBOMe part. Most phase II pathways

415 could be proposed for all three species with the exception of *O*-acetylation, *N*-acetylation, GSH
416 conjugation, and *O*-methylation. Again, the highest number of metabolites was identified in rat urine
417 probably due to the reasons described above.

418

419 3.5. Toxicological detection of 25B-NBOMe and 25C-NBOMe by SUSAs

420 3.5.1. GC-MS SUSA

421

Unfortunately, 25B-NBOMe and 25C-NBOMe and/or their metabolites could not be detected in rat urine after low dose administration (0.1 mg/kg BW). However, 25B-NBOMe and metabolites (Table 5) could be detected in the human urine sample by GC-MS SUSA. The compound ingested by the user was believed to be 2C-B, which typically requires a ten-fold higher dose compared to 25B-NBOMe [7]. Therefore, for acute and/or severe poisonings with NBOMes an intake could also be detected by GC-MS SUSA. 25C-NBOMe could only be detected after the high dose, enzymatic cleavage of conjugates, solid-phase extraction, and acetylation according to Welter et al. [31].

429

430 *3.5.2. LC-MS<sup>n</sup> SUSA* 

431

The LC-MS<sup>n</sup> approach could detect 25B-NBOMe and 25C-NBOMe and/or their metabolites in rat urine after low dosage (0.1 mg/kg BW) as well as in the authentic human urine sample. A list of the detected metabolites is given in Table 6. As already mentioned above, the differences of detected analytes in the human and rat urine samples could be caused by different doses and urine collection times.

437

438 *3.5.3. LC-HR-MS/MS SUSA* 

440 As expected, this approach was also able to reveal 25B-NBOMe and 25C-NBOMe and/or their 441 metabolites in rat urine after low dosage (0.1 mg/kg BW) as well as in the authentic human urine 442 sample. A list of the detected metabolites is given in Table 7. Again, the differences of detected 443 analytes in the human and rat urine samples could be caused by different doses and urine collection 444 times. Mostly due to the lethal overdose, the parent compound gave one of the most abundant signals 445 in the human urine sample. However, low dose rat urine studies showed that the parent compound 446 should not be expected in high amounts after recreational use. Therefore, it should not be used as the 447 only target for NBOMe urine screening.

448

#### 449 **4.** Conclusions

450

Both, 25B-NBOMe and 25C-NBOMe were extensively metabolized similar to 25I-NBOMe including *O*-demethylation, *O*,*O*-bis-demethylation, and hydroxylations as predominant pathways in humans and rats. This was in accordance to published human and animal in vitro and in vivo data. Several CYP isoenzymes were involved in formation of the main metabolites. An intake could be detected mainly via their metabolites by low and high resolution LC-MS SUSAs and by GC-MS SUSA only in overdose cases.

#### **Legends to Figures**

**Fig. 1** Metabolic pathways of 25B-NBOMe studied in rat (R) or human (H) urine as well as in incubations with human (L) or porcine (P) liver microsomes. Phase II metabolites: glucuronides (G), sulfates (S), glutathione conjugates (GSH), acetyl conjugates (AC), O-methyl conjugates (ME), acetyl conjugates combined with glucuronidation (AC+G), acetyl conjugates combined with sulfation (AC+S). Undefined position of *O*-demethylation or hydroxylation indicated by tildes. Numbering according to Tables S1 and S3.

**Fig. 2** Metabolic pathways of 25C-NBOMe studied in rat (R), mouse (M), or human (H) urine as well as in incubations with human hepatocytes (C). Phase II metabolites: glucuronides (G), sulfates (S), glutathione conjugates (GSH), acetyl conjugates (AC), *O*-methyl conjugates (ME), acetyl conjugates combined with glucuronidation (AC+G), acetyl conjugates combined with sulfation (AC+S). Undefined position of *O*-demethylation or hydroxylation indicated by tildes. Numbering according to Tables S2 and S4.

### Highlights

- First detailed Orbitrap-based study on the metabolism of two New Psychoactive Substances (NPS) and on detectability in urine by GC-MS and low and high resolution LC-MS techniques.
- The analytical novelty consists of the description of the identification power of various GC-MS and LC-(HR) MS techniques.
- The corresponding reference spectra and their interpretation are basis for routine drug testing worldwide of these NPS and thus of great relevance for all toxicologists.
- First comparison of metabolism data obtained from in vivo studies with three different species and from human in cellulo and in vitro studies.

- 1 Electronic Supplementary Data
- 2
- 3
- Metabolic fate and detectability of the new psychoactive substances 2-(4-bromo-2,5dimethoxyphenyl)-*N*-[(2-methoxyphenyl)methyl]ethanamine (25B-NBOMe) and 2-(4-chloro-2,5dimethoxyphenyl)-*N*-[(2-methoxyphenyl)methyl]ethanamine (25C-NBOMe) in human and rat urine
  by GC-MS, LC-MS<sup>n</sup>, and LC-HR-MS/MS approaches
  Achim T. Caspar, Simon D. Brandt, Andreas E. Stoever, Markus R. Meyer, Hans H. Maurer

**Table S1** List of 25B-NBOMe and its phase I metabolites together with the precursor mass (PM)
recorded in MS<sup>1</sup>, the corresponding characteristic fragment ions (FI) in MS<sup>2</sup>, the calculated exact
masses, the corresponding elemental composition, the deviation of the measured from the calculated
masses, given as errors in parts per million (ppm), and the retention times (RT) in minutes (min). The
metabolites were sorted by mass and RT.

**Table S3** List of all 25B-NBOMe phase II metabolites together with the precursor mass (PM) recorded in MS<sup>1</sup>, the corresponding characteristic fragment ions (FI) in MS<sup>2</sup>, the calculated exact masses, the corresponding elemental composition, the deviation of the measured from the calculated masses, given as errors in parts per million (ppm), and the retention times (RT) in minutes (min). The metabolites were sorted by mass and RT. Numbering according to Table 1 (AC = *N*-acetylation, GSH glutathione conjugation, ME = *O*-methylation, G = glucuronidation, S = sulfation, AC+G = acetylation combined with glururonidation, AC+S = acetylation combined with sulfation)

No.	M	etabolite and characteristic ions Measured accurate mass, <i>m/z</i>	Relative intensity in MS <sup>2</sup> , %	Calculated exact mass, <i>m/z</i>	Elemental composition	Error, ppm	RT, min

Table S4 List of all 25C-NBOMe phase II metabolites together with the precursor mass (PM) recorded in MS<sup>1</sup>, the corresponding characteristic fragment ions (FI) in MS<sup>2</sup>, the calculated exact masses, the corresponding elemental composition, the deviation of the measured from the calculated masses, given as errors in parts per million (ppm), and the retention times (RT) in minutes (min). The metabolites were sorted by mass and RT. Numbering according to Table 2 (AC = *N*-acetylation, GSH = glutathione conjugation, ME = *O*-methylation, G = glucuronidation, S = sulfation, AC+G = acetylation combined with glururonidation, AC+S = acetylation combined with sulfation)
