Intangible investments and voluntary delisting: Mass exodus of Chinese firms from US stock exchanges

Abstract

Purpose

Drawing on a cost-benefit perspective, this paper explores the relation between information asymmetry and the decision to delist from stock exchanges during periods of uncertainty. Specifically, it investigates the role of firms' intangible investments and the availability of alternative sources of finance on the decision to delist from foreign stock markets.

Design/Methodology/Approach

The study takes advantage of a natural experiment in which cross-listed Chinese firms facing uncertainty in US markets due to widespread allegations of accounting fraud, decide on whether to remain listed or voluntarily delist. Here, the decision to delist is modeled as a function of the level of information asymmetry between firms and their stakeholders, and the availability of alternative financing, while controlling for other drivers of firms' delisting decision. The data used in the empirical analyses covers a hand-collected sample of 91 Chinese firms voluntarily delisting from US stock markets between 2010 and 2016. This sample is matched with an equal sample of Chinese firms, which remained listed in US stock markets during the same period. A probit regression model accounting for fixed-effects is used. The study also uses probit model interaction effects to capture the mediating effect of alternative financing on the intangibles-delisting nexus.

Findings

There is a significant positive relationship between investments in intangible assets and firms' decision to delist. Moreover, the evidence suggests that the positive intangibles-delisting nexus is accentuated by the availability of alternative sources of financing. Collectively, the results are consistent with the theoretical argument that the higher information asymmetry associated with intangible assets may increase the cost of staying listed on stock exchanges, particularly, in periods of uncertainty (captured in this study by accounting fraud allegations targeting cross-listed firms). The results have important implications for corporate managers, capital market participants, and policy makers.

Originality/Value

The study exploits a unique natural experimental setting to explore why cross-listed firms delist. The underlying theoretical framework to explain delisting is new. This framework captures the role of information asymmetry, uncertainty and alternative financing in explaining the cost and benefits of remaining listed on a foreign market.

Key words: Voluntary delisting; Intangible assets; Information asymmetry; US stock exchange; China.

1. Introduction

The liberalisation of capital markets, as well as, technological progress over the last three decades has created new opportunities for firms to seek development and growth beyond their national borders. Prior studies (see e.g., Merton, 1987; Stulz, 1999; Errunza and Miller, 2000; Karolyi, 2006; Bharath and Dittmar, 2010; Eng and Ling, 2012) have explored the motivations of foreign firms listing in US stock markets. The extant research suggests that foreign firms cross-list into the US market to gain access to lower cost of capital (Errunza and Miller, 2000; Bharath and Dittmar, 2010), greater investor recognition (Merton, 1987), or as a commitment mechanism to the stricter US regulations and investor protection rights (Stulz, 1999; Karolyi, 2006; Eng and Ling, 2012). Clearly, besides stricter regulations, there are other costs associated with listing on more sophisticated markets, most notably, greater information disclosure requirements (Eng and Ling, 2012) and increased scrutiny by stakeholders such as analysts and the press. While the extant research explores the motivations underlying firms' listings in foreign markets, it is unclear how these associated cost influences delisting decisions. The case of cross-listed Chinese firms in US markets provides a natural setting to explore this issue.

The China Securities Regulatory Commission, established in 1992, allowed Chinese firms to cross-list. This led to a surge in the number of Chinese firms listing in foreign markets, particularly in the US. As in Figure 1, the number of Chinese firms listing on US markets increased successively each year from 2001, reaching its peak in 2007. Noticeably, Chinese firms' listings on US markets significantly reduced to 11 in 2011, representing a 96% decline from the previous year. Concurrently, as shown in Table 2, a wave of voluntary delisting also emerged.¹ Recent figures suggest that between 2010 and 2015, there were over 80 delisting announcements from US stock exchanges involving

1
2
3 Chinese firms. This wave of delisting has been attributed to loss of investor confidence following
4 reports of fraudulent accounting practices in some Chinese US-listed firms (Song and Zeng, 2012).
5
6

7
8 **[INSERT FIGURE 1]**
9

10 Notably, a survey report released by Muddy Waters Research Company in June 2010 suggested
11 that some US-listed Chinese firms (e.g. Orient Paper) were involved in fraudulent financial reporting.
12
13 Similarly, Citron Research reported accounting fraud and bribery scandals involving Evergrande Real
14 Estate Group (a high profile Chinese firm). Even though these claims were unsubstantiated,
15 Evergrande Real Estate Group lost HK\$8 billion of its market value. Arguably, these scrutiny,
16 allegations, exposure and suspicion relating to accounting fraud instigated a mass exodus of Chinese
17 firms from US stock markets (see Song and Zeng, 2012; Liu *et al.*, 2016; Zhang, 2012). Interestingly,
18 some Chinese firms maintained their US listing.

24
25
26
27
28
29

30 The case of Chinese firms delisting from US exchanges between 2010 and 2016 creates a natural
31 experimental setting to explore the decisions of cross-listed firms under uncertainty. This article,
32 therefore, examines whether firms with a higher perceived cost of cross-listing embark on delisting
33 for precautionary reasons. Here, the paper utilises firm-level intangible investments (which capture
34 the level of information asymmetry between firms and stakeholders) to proxy for the level of scrutiny
35 that firms potentially face when investors suspect accounting fraud. Drawing from the cost-benefit
36 perspective on why firms become public (see, Maupin *et al.*, 1984; Kaplan, 1991; Bharath and
37 Dittmar, 2010; Chaplinsky and Ramchand, 2012), the paper argues that when investors (notably US-
38 based) associate cross-listed (Chinese) firms with accounting fraud, the cost of remaining listed
39 becomes asymmetrically higher for those firms with high information asymmetry (proxied by
40 intangibles).² Consequently, it is posited that the presence of intangible assets increases (reduces) the
41
42

1
2
3 costs (net benefits) of being listed on overseas' markets, resulting in a higher propensity to delist in
4
5
6 times of uncertainty (i.e., when cross-listed firms are susceptible to accounting fraud allegations). To
7
8 corroborate this benefit-cost argument, the paper considers how the delisting decision is shaped by a
9
10
11 firm's propensity to secure alternative private funding.
12

13 The present article contributes to the scant but growing literature on public-to-private
14
15 transactions (PTPs) by providing evidence that possibly explains why cross-listed firms faced with
16
17 uncertainty respond differently, i.e., some remain listed while others delist. Thus, the study's analysis
18
19 documents the fundamental drivers (beyond the investor confidence crisis) of firms' voluntary
20
21 delisting decisions. Moreover, it contributes to this PTPs literature which has largely focused on
22
23 transactions of firms in the advanced economies of the US and the UK, often using dated data (see,
24
25 e.g. Renneboog et al., 2007; Marosi and Massoud, 2007; Pour and Laser, 2013), with empirical
26
27 studies on firms from emerging economies like China being rare.³
28
29
30
31
32

33 This paper relates to, but also differs from recent research by Chaplinskya and Ramchand (2012)
34
35 and Pour and Laser (2013). Chaplinskya and Ramchand (2012) examine the factors motivating
36
37 foreign firms to delisting from US stock exchanges over the period 1962-2006, while the current
38
39 article specifically considers the delisting decisions of Chinese firms from US markets for a more
40
41 recent period (2010-2016) when there was a foreign investor confidence crisis. Similarly, Pour and
42
43 Laser (2013) analyse the motives and market valuations of voluntary delisting from the London Stock
44
45 Exchange during 1995-2009. They mainly focus on firms' capital structure rebalancing as a driver of
46
47 their delisting decisions, whereas the primary focus of the current study is on the role of intangible
48
49 assets in driving the delisting decisions of Chinese firms from US stock exchanges. Focusing on
50
51 intangible assets is important given the increasing prominence of intangible assets vis-à-vis
52
53
54
55
56
57
58
59
60

1
2
3 investments in capital expenditure by firms in recent years (Anagnostopoulou, 2008; Borisova and
4
5
6 Brown, 2013). For example, Borisova and Brown (2013) report the ratio of R&D spending to total
7
8 assets in 2008 to be around 10% compared to a capital expenditure ratio of about 4% for publicly
9
10 listed companies with coverage in the *Compustat* database.
11
12

13 The results, based on a probit analysis of 91 voluntary delisting announcements by Chinese firms
14
15 listed on US markets during the seven-year period, 2010 to 2016, and a carefully selected control
16
17 sample, show that investments in intangible assets are a significant driver of firms' voluntary delisting
18
19 decisions, after controlling for other determinants of the delisting decision. Specifically, the results
20
21 show a delisting probability of 11% for an average firm in the sample that undertakes average levels
22
23 of intangible investments. The paper further finds the delisting probability to be even higher, ranging
24
25 from 20-22%, for those firms with the topmost intangible investments (e.g. firms with above-median
26
27 or top 25% investments in intangibles). Moreover, the evidence suggests that firms with higher
28
29 intangible investments are more likely delist from stock markets when they have alternative sources
30
31 of financing such as a prior successful equity issue or a thriving internal capital market.
32
33
34
35
36
37

38 The results align with the article's proposed theoretical framework. The framework contends that
39
40 the higher information asymmetry and valuation challenges associated with intangible investments
41
42 (Anagnostopoulou, 2008) increase (decrease) the costs (net benefits) of remaining listed on stock
43
44 exchanges, particularly when there is market uncertainty. The results are consistent with prior studies
45
46 (e.g. Maupin *et al.*, 1984; Kaplan, 1991; Bharath and Dittmar, 2010; Chaplinskya and Ramchand,
47
48 2012) suggesting that firms tend to consider both costs and benefits in making their delisting
49
50 decisions. Finally, the results have important implications for corporate managers, capital market
51
52 participants, and policy makers.

3 The rest of the paper is organised as follows. Sections 2 and 3 describe the context of the study
4
5 and develop testable hypotheses. Section 4 describes the data and empirical methods. Section 5
6
7 presents and discusses the results, and Section 6 concludes the paper.
8
9

10 11 12 13 **2. The impact of accounting fraud on investor confidence**

14 15 16 *2.1 US analysts and accounting fraud*

17
18 One of the features of becoming a public firm in advanced economies is the intense media and
19
20 analysts' coverage/scrutiny (Eng and Ling, 2012). These analysts together with the press play an
21
22 important role as an information intermediary in financial markets by often identifying corporate
23
24 financial malfeasance and broadcasting them. Miller (2006) describes them as the "watchdog" of
25
26 corporate America. Existing research on the relations between information intermediaries (e.g. the
27
28 press, analysts, etc.) and commerce suggests that these "watchdogs" do not only shape public
29
30 perceptions of firms, but they also have a significant influence on financial market participants
31
32 (Zingales, 2000; Jensen, 1979; Miller, 2000). Miller (2000) shows that in 29% of the cases of
33
34 accounting violations that he studied in his US sample, the press had published articles regarding
35
36 accounting fraud prior to a public acknowledgment by the firm or US Securities and Exchange
37
38 Commission, and the markets reacted negatively in most cases. He concludes that the press, through
39
40 its exposure of accounting fraud, actually provides investors with valuable information, especially
41
42 when their reports are backed by some investigations/research.
43
44
45
46
47
48
49

50 Prior literature suggests that analysts' and press reports on accounting irregularities in public
51
52 corporations adversely affect the fortunes of the public firm through loss of reputation (Karpoff *et al.*,
53
54 2008), and ultimately, substantial decreases in stock prices (Feroz *et al.*, 1991; Dechow *et al.*, 1996;
55
56
57
58
59
60

1
2
3 Miller, 2000). This suggests that besides the upfront cost of going public (e.g. admission fees), firms
4
5 face additional risk/cost of intense scrutiny, particularly in relation to potential accounting fraud.
6
7
8 Clearly, these additional costs may eventually outweigh the benefits of remaining listed (for example,
9
10 in periods of high uncertainty), motivating some listed firms to delist.
11
12
13

14 15 16 2.2 Recent US analysts' reports of accounting frauds in listed Chinese firms 17

18 High-profile allegations of accounting fraud involving Chinese firms in US stock markets in 2010
19
20 and 2012 increased levels of uncertainty and, perhaps, the fraud-related listing cost, for this particular
21
22 group of firms. The first major allegation was published on 28th June 2010⁴ by Muddy Waters
23
24 Research LLC (Muddy Waters), a US privately-held investment firm that specialises in conducting
25
26 investigative research and due diligence on public companies. Muddy Waters reported of egregious
27
28 accounting fraud in Orient Paper Inc. (ONP)⁵, a Chinese company listed on the New York Stock
29
30 Exchange, and boldly concluded as follows: "*We are confident that ONP is a fraud. Its purpose is to*
31
32 *raise and misappropriate tens of millions of dollars.*" The report cited specific accounting
33
34 irregularities including ONP overstating its 2008 and 2009 revenue by 27 and 40 times respectively,
35
36 overvaluing its assets by at least 10 times, and misappropriating approximately US\$30 million since
37
38 October, 2009, among others. The report concluded with a "*strong sell*" recommendation. This
39
40 incident did not just cause substantial damage to ONP, but it also heightened market fears that other
41
42 Chinese public corporations may be involved in similar fraudulent accounting practices (Zhang,
43
44 2012).
45
46
47
48
49
50
51

52 Two years later (on 21st June 2012⁶), Citron Research, a US-based analyst, made another high
53
54 profile financial fraud allegation against Evergrande Real Estate Group Limited (Evergrande), a
55
56
57
58
59
60

1
2
3 public Chinese firm. Citron Research claimed that: "...*Evergrande is essentially an insolvent*
4 *company that has consistently presented fraudulent information to the investing public*". The report
5
6 detailed that Evergrande used bribery of local government officials and various "*accounting tricks*" to
7
8 hide its insolvency, and that a total write-down of RMB 71 billion is required to move the company's
9
10 reported equity from RMB 35 billion to *negative* RMB 36 billion. While the report was
11
12 unsubstantiated, on the day of the accounting fraud allegation, the company's share closed 11.4%
13
14 down, compared to only a 1.3% decline on the market index. The allegation wiped-off over HK\$8
15
16 billion from Evergrande's market value, causing panic among some Chinese public companies and
17
18 possibly motivating them to exit US stock exchanges (Liu *et al.*, 2016). What followed these
19
20 allegations was a reduction in the number of Chinese firms listing on US stock exchanges and a
21
22 concurrent increase in the number of voluntary delisting.
23
24
25
26
27
28
29
30
31
32

33 **3. Related literature and hypotheses development**

34 *3.1 Why do firms delist?*

35
36
37 The extant literature advances several reasons to explain firms' decision to delist. Firstly, from an
38
39 agency perspective, managers with free-cash flows and low growth prospects might chose to waste
40
41 cash on non-value-increasing projects (Jensen, 1986; Elmagrhi *et al.*, 2017). Delisting can curb
42
43 agency conflicts by paying out excess cash or leveraging to repurchase stock (Lehn and Poulsen,
44
45 1989; Kieschnick, 1998). Secondly, from a governance perspective, powerful CEOs might delist,
46
47 possibly, to avoid the intense scrutiny and regulation associated with being a public firm (Weir *et al.*,
48
49 2005a; Weir *et al.*, 2005b; Manuela and Giovanna, 2012).
50
51
52
53
54

55 Thirdly, from an information asymmetry perspective, managers may choose to delist when they
56
57
58
59
60

1
2
3 perceive their stock as being undervalued, limiting their ability to raise finance (e.g. Maupin *et al.*,
4
5
6 1984, Renneboog *et al.*, 2007; Weir *et al.*, 2005b). Firms have also been shown to delist for pragmatic
7
8 reasons, e.g., low trading volumes in US markets, the ability of home markets to meet capital their
9
10 capital needs, and increased cost and complexity of US market regulations such as the Sarbanes-
11
12 Oxley Act (Marosi and Massoud, 2007; Chaplinsky and Ramchand, 2012; Bharath and Dittmar, 2010;
13
14 Pour and Laser, 2013).
15
16
17
18
19

20 21 *3.2 The role of intangible investments in corporate delisting decisions and hypotheses*

22

23 Firms, perhaps, evaluate the net benefit of remaining listed in a dynamic context where both firm-
24
25 level and country-level (both home and foreign) factors change over time, when deciding whether to
26
27 remain listed. Within this context, the allegations of accounting fraud involving Chinese firms listed
28
29 on US markets may have increased investors' uncertainty over the true value of Chinese public firms,
30
31 particularly, for firms with high levels of difficult-to-value intangible assets. Chinese firms, within this
32
33 context, also face heightened uncertainty due to increased scrutiny by analysts who may provide
34
35 wrong forecasts (Anagnostopoulou, 2008). These information asymmetries and uncertainties reduce
36
37 investors' willingness to fund investments, and consequently reducing firms' access to new equity
38
39 and/or increasing their underlying cost of capital. This paper argues that this tension, partly, offsets the
40
41 expected benefits of remaining listed on US markets.
42
43
44
45
46

47 Empirical evidence on the role of intangible assets on corporate delisting decisions is rare in the
48
49 US- and UK-focused literature, and virtually non-existent for emerging economies. The few studies
50
51 that include R&D or intangibles in their analysis have them as control variables to proxy for
52
53 information asymmetry, and report mixed results. For example, Pour and Laser (2013) provide weak
54
55
56
57
58
59
60

1
2
3 evidence for a positive association between intangible assets and firms' delisting decisions, but
4
5
6 Bharath and Dittmar (2010) and Marosi and Massoud (2007) find that the estimated coefficients for
7
8 intangible asset ratios are insignificant, implying that information asymmetry is not a factor in the
9
10
11 delisting decision.

12
13 The current article contributes to this literature by hypothesising that, within the context of
14
15 heightened uncertainty in US stock markets over Chinese public firms following recent series of
16
17 reports of accounting fraud, the levels of intangible investments played a crucial role in Chinese firms'
18
19 decision to delist from the US stock exchanges. This is primarily because firms' intangible
20
21 investments, within this context, impede their ability to issue new equity at a reasonable cost (i.e. one
22
23 of the benefits of being listed), thereby, shaping their overall costs and net benefits of remaining
24
25 listed. By their very nature, intangible investments attract greater analyst coverage and are more
26
27 susceptible to analyst forecast errors, thereby, having serious consequences on firm valuations
28
29 (Anagnostopoulou, 2008). Barth *et al.* (2001) find that analyst coverage is significantly greater for
30
31 R&D-intensive firms and industries. Amir *et al.* (2003) also find analyst forecast errors to be
32
33 positively related to investments in intangibles, demonstrating analysts' lack of understanding of the
34
35 implications of intangibles on firms' future profitability.

36
37 Further and in response to the valuation difficulties associated with intangible assets, accounting
38
39 rules tend to be stringent on intangible investments, requirement frequent assessments and charging
40
41 impairment losses, but also creates room for managerial manipulations of financial statements. Watts
42
43 (2003) notes that that the current global accounting standard on goodwill and impairment (IFRS 3)
44
45 which allows for managerial discretion may motivate managerial optimism and earnings management,
46
47 and worsen investors' suspicion of fraud in connection with intangible assets. Consistent with this
48
49
50
51
52
53
54
55
56
57
58
59
60

prediction, Sun and Zhang (2017) find a negative relationship between goodwill impairment losses and bond credit ratings, suggesting that firms with goodwill impairment losses (i.e. high intangible-firms) obtain lower credit ratings. In an attempt to avoid credit ratings downgrade, for example, managers may be motivated to understate impairment losses. Based on a sample of Australian firms, Bepari and Mollick (2017) report that the adoption of goodwill impairment approach (under IFRS 3) has decreased the frequency and the amount of goodwill write-offs that would have been required under the systematic amortisation regime (old standard).

Collectively, the literature suggests that investments in intangibles are inherently risky, more susceptible to managerial manipulation and accounting fraud, attract greater analyst coverage, and are subject to greater analysts' forecast errors. Therefore, in periods of general market uncertainty, public firms with higher investments in intangibles may incur greater costs of remaining listed, and are (thus) more likely to delist. Accordingly, the first hypothesis is formulated as follows:

***H1:** Investment in intangible assets is positively associated with corporate delisting decisions.*

3.3 Intangibles-delisting nexus: The accentuating effect of alternative financing sources

The nexus between the decision to delist and intangible investments is likely to be accentuated by the availability or otherwise of alternative sources of financing for firms. For listed firms with high intangibles but without the ability to fund their intangible investment projects internally or from external debt, their net benefits for remaining listed may be relatively higher, making them less likely to delist. On the contrary, when firms have suitable and less costly means of financing (e.g., from accumulated reserves, prior equity issues, or even from banks), their net benefit of remaining listed is

reduced, making them more likely to delist from stock markets, in periods of high market uncertainty.

Since large, mature, and established firms tend to be able to access alternative funding sources (Muller and Zimmermann, 2008; Czarnitzki and Hottenrott, 2011), we expect such firms to have a greater likelihood to delist when they have high levels of intangible assets. Therefore, the second hypothesis is proposed for testing:

H2: The positive intangibles-delisting nexus is accentuated by firms' ability to finance investments from alternative sources (e.g. accumulated profit, prior equity issues, etc.).

4. Data and Methods

4.1 Data

To test Hypotheses 1 and 2, a sample of all privatisation announcements over seven fiscal years (2010 and 2016) by Chinese firms listed on major US stock exchanges is collected, regardless of whether the privatisation process completed successfully. This was to reflect the objective of investigating the role of intangible investments on firms' *decision to delist*. It is considered that public privatisation announcements by firms are preceded by an earlier decision to delist. However, for simplicity, the paper refers to these firms making privatisation announcements as delisting firms (or delist sample).

The data on Chinese firms delisting from US stock exchanges, specifically information on firms' name and dates of delisting announcement, are hand-collected from three prominent Chinese financial web-based platforms (*iMeigu*, *Hexun* and *Sina Finance*).⁷ All the other data for the study including the IPO dates and financial/accounting data are collected from the *Wind Financial Database*.⁸ The search identified 94 US-listed Chinese companies that had publicly announced their decision to delist

1
2
3 during 2010-2016, an average of 13 per year. It is worth noting that Chaplinsky and Ramchand (2012)
4
5 report an average annual delisting of 16 *foreign* firms from US markets between 1962 and 2006.
6
7 These statistics suggest disproportionately higher delisting announcements by Chinese firms from US
8
9 exchanges in recent years relative to other foreign firms.
10
11

12
13 Due to data constraints, three of the 94 delisting firms drop out of the sample, leaving a final
14
15 sample of 91 Chinese firms delisting from four major US stock exchanges⁹ over the 2010-2016
16
17 period. Table 1 presents the distribution of the sample by stock exchange and industry of the delisting
18
19 firms. Over half of the sample firms (58%) exit the NASDAQ, with another 32% exiting the NYSE.
20
21 The remaining 10% of the sample predominantly delist from other OTC markets. Perhaps, the
22
23 relatively less restrictive listing requirements of NASDAQ make it a preferred capital market for
24
25 Chinese firms. Noticeably, almost half (44%) of the sample firms are from the Information
26
27 Technology industry which generally tends to be R&D-intensive. This provides some early anecdotal
28
29 evidence of a possible link between intangible investments and corporate delisting transactions.
30
31
32
33

34
35 **[INSERT TABLE 1 HERE]**
36
37

38 Table 2 displays the sample distribution by year of delisting announcement, year of listing (i.e.
39
40 IPO), as well as, by the number of trading years firms had been on the stock exchange before
41
42 delisting. As can be seen, the highest number of delisting announcements (30) was observed in 2015,
43
44 which coincides with the year immediately following the accounting fraud allegation by Citron
45
46 Research against Evergrande. Similarly, the second and third highest numbers of delisting
47
48 announcements were observed within the two-year period (2011-2012) after Muddy Waters reported
49
50 of fraudulent accounting in Orient Paper Inc. in 2010. These statistics, perhaps, provide some basis for
51
52 public opinion that the recent wave of delisting of Chinese firms from US exchanges is a response to
53
54
55
56
57
58
59
60

the accounting fraud allegations involving Chinese firms.

IPO information suggests that the sample firms were listed in US stock exchanges between 2000 and 2014, with the highest listing in any single year (27 firms) observed in 2007. Only 17 firms (19%) listed on US markets after 2010 (post-ONP fraud allegations) and none listed after 2014 (post-Evergrande fraud allegations). Again, these statistics suggest that the accounting fraud allegations might have reduced the appetite of Chinese firms for US stock markets. Finally, at the time of delisting, majority of sample firms (almost 70%) had traded on the US markets for five years or less, suggesting that most sample firms may lack sufficient experience of operating in US stock exchanges.

[INSERT TABLE 2 HERE]

4.2 Empirical model

The main empirical approach of the paper is a probit regression model predicting the probability of a firm delisting from the stock exchange conditional on its intangible investments and a set of control variables. The dependent variable is equal to one for voluntary delisted firms and zero for control firms. Similar to previous studies (e.g. Pour and Laser, 2013), each Chinese delisted firm (delist sample) is matched with a Chinese firm that remained listed (control sample) on US markets based on industry, size, and IPO date. The final empirical analysis is based on a sample of 91 delisting firms and 91 non-delisting controls, i.e., an overall sample of 182 observations.

The baseline probit model for the empirical analysis is specified below in Eq. (1):

$$P_{it}(\text{Delist} = 1) = \beta_1 + \beta_2 IAR_{it-1} + \sum_{k=1}^k X_{kit-1}^1 \beta_k + u_{it} \quad \text{Eq. (1)}$$

where: P_{it} refers to the probability of firm i delisting from the US stock exchange, the β s represent the intercept (β_1), the coefficient for intangible assets ratio (IAR) (β_2), and for the control variables (β_k)

1
2
3). The u_{it} is the random error term assumed to be serially uncorrelated and homoscedastic. IAR_{it-1}
4
5
6 represents a one-period lagged value of the firm's intangible investments, the primary variable of
7
8 interest, which is predicted to be positively related to corporate delisting decision (HI). Finally, X_{kit-1}
9
10 in Eq. (1) represents one of the following lagged k control variables that may affect firms' decision to
11
12 delist. The explanatory variables are lagged to minimize reverse causality problems and to increase
13
14 the likelihood that causality flows from the explanatory variables to the dependent variable
15
16 (endogeneity).
17
18
19

20
21 The control variables are defined in Table 3. First, the number of listing years (i.e. the period
22
23 between the IPO date and the delisting date) is included to control for two effects; the experience
24
25 effect and the stability/financing effect. Firms that have been on the market for long may be more
26
27 experienced in dealing with crisis and may thus be less likely to panic and exit the stock market in
28
29 challenging times. Alternatively, these firms may represent mature, established firms with more
30
31 analysts' coverage and alternative funding sources (Merton, 1987; Baker *et al.* 2002; Lang *et al.*,
32
33 2003), and may therefore have a higher likelihood to delist should they consider the cost of remaining
34
35 listed to be too high. The financing effect is further controlled for by including additional variables
36
37 that may capture varying aspects of firms' ability to source alternative capital since obtaining
38
39 financing is one of the primary reasons why firms become public (Reese and Weisbach, 2002). The
40
41 financing variables include: (1) return on equity, proxying for current profitability, which may
42
43 contribute to retained earnings for internal financing; (2) financial leverage to proxy for borrowing
44
45 ability; (3) seasoned equity offerings as a proxy for firms' attractiveness to investors and possible
46
47 presence of reserves from prior equity issues; and (4) log of total assets as a proxy for the size of
48
49 firms' internal capital market.¹⁰

[INSERT TABLE 3 HERE]

Another set of controls included in the regression aims to account for firms' growth prospects. Firms with higher growth prospects may need more funds to finance their growth opportunities and may thus be less willing to delist (Bancel and Mittoo, 2008; Aslan and Kumar, 2011; Chaplinsky and Ramchand, 2012). Chaplinsky and Ramchand (2012) show that growing firms from emerging market economies that need external funding to support their growth are willing to incur higher costs of listing in the US. This effect is captured by including the 3-year average operating profit growth rate, capital expenditure intensity, net assets per share, and market-to-book ratio. The market-to-book ratio may also proxy for misvaluation (i.e. over- or under-valuation) of the firm resulting from information asymmetry.

Further, as discussed in sub-section 3.1, public firms potentially suffer from agency problems that emanate from excessive CEO power and/or free cash flow (Jensen, 1986; Elmagrhi *et al.*, 2017), and privatisation may serve as a tool for aligning managerial interests with those of shareholders. Therefore an indicator variable for CEO duality (i.e. CEOs doubling up as the Board Chair) and free cash flow variable are included to control for the agency effect on delisting. The free-cash flow variable may also pick up some alternative financing effect. Lastly, year fixed-effect is controlled for by including dummies for the delisting years to account for macroeconomic factors that may influence corporate delisting transactions. Industry fixed-effect was not controlled for in the regression model since the peer firms were selected from the same industries as the delist sample.

The baseline probit regression model in Eq. (1) is modified when testing $H2$ and when conducting additional robustness checks. For example, the model for testing $H2$ contains an additional interaction term between IAR and a financing variable, as shown in Eq. (2):

$$P_{it}(\text{Delist} = 1) = \beta_1 + \beta_2 IAR_{it-1} + \beta_3 (IAR * Financing)_{it-1} + \sum_{k=1}^k X_{kit-1}^1 \beta_k + u_{it} \quad \text{Eq. (2)}$$

5. Empirical results and discussion

5.1 Descriptive statistics and bivariate analyses

Panel A of Table 4 summarises the descriptive statistics for the study's variables for the full sample and also separately for the delist and control samples. As displayed in the Table, the firms in the delist sample have a substantially higher investments in intangible assets compared with their counterparts in the control sample. Specifically, the intangible assets as a proportion of total assets is 11% for the delist sample relative to 7.9% for the control sample, with the difference of 3.1% being statistically significant at the 10% level. This again provides early evidence in support of *H1*, in that, intangible investments seem to be positively associated with firms' delisting decisions.

Although the differences between the delist and control sample for the other variables were not statistically significant, firms that delisted from the stock exchanges generally had lower listing years, market-to-book ratio, profitability growth rate, free cash flow, net assets per share, and capital expenditure intensity. These statistics suggests that delisting firms may be more naïve (inexperienced in stock market dealings), undervalued, with limited growth prospects. However, delisting firms appear to have better prospects of obtaining alternative financing by being larger and more attractive to investors (due to recent success in seasoned equity offerings), as well as having greater current profitability and leverage levels. These patterns are largely in line with *H2*.

[INSERT TABLE 4 HERE]

In Panel B of Table 4, the correlation matrix for the variables is presented, and observably, there is a statistically significant positive association between intangible investments and delisting

1
2
3 transactions. There also seem to be a positive (negative) association between corporate delisting
4
5 activities and CEO duality, profitability, leverage, firm size, and seasoned equity offerings (listing
6
7 years, market-to-book ratio, profitability growth, free-cash flow, net assets per share, and capital
8
9 expenditure), albeit not statistically significant. Panel B of the table also shows low levels of
10
11 correlation among the explanatory variables (all correlation coefficients are below 0.5), suggesting
12
13 that multicollinearity may not pose any serious limitations on the multivariate regression analysis in
14
15
16
17
18 the next section.
19
20
21
22

23 5.2 Multivariate analysis and discussions

24
25 Table 5 presents the results for the probit regressions for the effect of intangibles on corporate
26
27 delisting decisions. The marginal effects (reported in the Table), relate to the partial effect of each
28
29 explanatory variable on the probability of delisting, and help to directly interpret the coefficients as
30
31 probabilities (see Agyei-Boapeah, 2017; Pour and Lasfer, 2013). In Model 1, the intangible asset ratio
32
33 (IAR) is positive and statistically significant at the 1% level (coefficient=0.029; p -value=0.002),
34
35 suggesting that Chinese firms with high levels of intangible investments were more likely to delist
36
37 from the US stock exchanges during the sample period. The marginal effect of the intangibles (IAR) is
38
39 0.011, implying that a unit increase in intangible investment increases the probability of delisting by
40
41 1.1%, on average. With the average sample firm having 9.5% of assets in intangibles, this result
42
43 suggests a delisting probability of 11% (i.e. $0.011 * 9.5$) for a firm undertaking average levels of
44
45 investments in intangible assets.
46
47
48
49
50
51

52 The positive relationship between intangible investments and the delisting decision is consistent
53
54 with theoretical predictions. That is, increased levels of intangible investments appear to be associated
55
56
57
58
59
60

1
2
3 with increased cost of remaining listed on stock exchanges, which emanates from an increased risk of
4
5 financial statement manipulations by managers (Watts, 2003), greater analyst coverage (Barth *et al.*,
6
7 2001) as well as higher analysts' forecast errors (Amir *et al.*, 2003), and higher information
8
9 asymmetry (Muller and Zimmermann, 2009; Czarnitzki and Hottenrott, 2011), leading to the
10
11 undervaluation/mispricing of such firms (Anagnostopoulou, 2008) and potential losses to their
12
13 shareholders (Weir *et al.*, 2005b). In addition, the difficulties in objectively valuing intangible assets
14
15 as well as their lack of collateral value appear to make it difficult for high-intangible firms to access
16
17 capital from investors when the market faces heightened uncertainty. Consequently, these factors
18
19 together increase (reduce) the costs (net benefits) of staying listed on the exchange for high-intangible
20
21 firms, causing them to delist from the stock exchange.
22
23
24
25
26
27

28 Overall, the broad implications of the findings are consistent with the generic cost-benefit
29
30 theoretic framework for understanding public-to-private transactions (see Marosi and Massoud, 2007;
31
32 Bharath and Dittmar, 2010). For example, Bharath and Dittmar (2010) posit that since the decision to
33
34 go public is a trade-off between the costs and benefits of listing, the delisting decision is also likely to
35
36 be taken when the costs of listing exceed the benefits.
37
38
39

40 **[INSERT TABLE 5 HERE]**
41

42 In the next three Models of Table 5, tests for robustness of the results are conducted by measuring
43
44 the primary explanatory variable, intangible investments, using different indicator variables. First, in
45
46 Model 2, high-intangible firms are defined to include a dummy for firms with above-median
47
48 intangible investments. Similarly, in Models 3 and 4, the definition of high-intangible firms is
49
50 restricted to include only firms in the top 40% and 25% brackets for intangible investments,
51
52 respectively. The results, reported in Table 5, confirm the strong positive impact of intangibles on the
53
54
55
56
57
58
59
60

1
2
3 ultimate delisting decisions of firms. Specifically, the probability of delisting from stock exchanges
4
5 increases by between 19-22% if firms are within the top tier for intangible investments. Collectively,
6
7 these results offer empirical support for *H1*, as well as provide further support to the findings of
8
9 previous studies (e.g. Marosi and Massoud, 2007; Chaplinskya and Ramchand, 2012; Pour and Laser,
10
11 2013), which suggest that firms consider the costs and net benefits of listing in deciding whether to
12
13 remain or delist from stock markets. Pour and Laser (2013) provide evidence to suggest that firms
14
15 delist voluntarily from the London Stock Exchange when they fail to benefit from listing by not
16
17 raising sufficient equity capital to rebalance their capital structure. In the US, Marosi and Massoud
18
19 (2007) and Chaplinskya and Ramchand (2012) find that the Sarbanes–Oxley Act (SOX) and the
20
21 associated compliance costs are major determinants of corporate delisting decision by increasing the
22
23 listing costs of public firms. In comparison, the findings of the present paper imply that listing costs
24
25 (benefits) are higher (lower) for firms with higher investments in intangible assets.
26
27
28
29
30
31

32
33 In terms of the control variables, firms that have been listed for more years and those with higher
34
35 growth prospects (i.e., market-to-book value, operating profit growth, net assets per share) seem to
36
37 have a significantly reduced probability of delisting. Also, current profitability (measured as return on
38
39 equity) appears to consistently have a positive and significant impact on the decision to delist. These
40
41 results are generally in line with prior studies such as Bharath and Dittmar (2010) and Pour and Lasfer
42
43 (2013).
44
45
46

47
48 Turning attention to the second empirical issue (H2), there is evidence that the presence of
49
50 alternative sources of financing intangible projects may influence the intangibles-delisting nexus, as
51
52 shown in Table 6. As noted in section 4 [in specifying Eq. (2)], the IAR is interacted with each of the
53
54 explanatory variables which could represent an alternative source of financing, namely; listing years,
55
56
57
58
59
60

1
2
3 return on equity, free cash flow, leverage, firm size, and seasoned equity offerings. The results are
4
5 reported in Models 1-6 of Table 6. First, the number of years for which a firm has been listed (listing
6
7 years) is negative and statistically significant at 99% confidence level, implying that Chinese firms
8
9 with more experience of the stock exchange dealings are more likely to remain listed. More
10
11 importantly, the coefficient of the interaction term (IAR*Listing years) is positive and statistically
12
13 significant at 5% level, suggesting that even the experienced firms decide to delist when they have
14
15 high investments in intangible assets. To the extent that these experienced firms with greater listing
16
17 history, analyst coverage, and market exposure are more attractive to investors and could easily obtain
18
19 capital elsewhere (see Agyei-Boapeah, 2015), then these results provide empirical support for *H2*.
20
21 Agyei-Boapeah (2015) finds UK acquiring firms with significant experience in foreign markets to
22
23 reap some financing advantages over their inexperienced counterparts.
24
25
26
27
28
29

30
31 However, in Models 2-4, the interaction terms [(IAR*Return on Equity); (IAR*Free cash flow);
32
33 and (IAR*Financial leverage)] though positive, lack statistical significance at conventional levels, and
34
35 therefore inconsistent with *H2*. It is, however, possible that the current levels of profitability and free
36
37 cash flow are not sufficient to fund intangible investment projects, thus, making firms reluctant to
38
39 delist. Similarly, it may be that bondholders are less willing to fund intangible investments because of
40
41 their lack of collateral value. Consequently, borrowing may not really be an alternative source of
42
43 financing intangible assets. However, Czarnitzki and Hottenrott (2011) show that R&D projects are
44
45 more likely to be funded from internal capital markets that are associated with large, diversified firms
46
47 (Agyei-Boapeah, 2017). Consistent with this conjecture and *H2*, the results in Model 5 show that
48
49 high-intangible firms are more likely to delist from stock exchanges when they are large and likely to
50
51 have a sizeable pool of internal capital market to finance their intangible investments internally.
52
53
54
55
56
57
58
59
60

1
2
3 Moreover, the individual effect of intangibles (without internal capital market) and firm size (without
4
5
6 high intangible investments) on delisting decision are statistically negative, suggesting that even the
7
8 high-intangible firms stay listed if they may not be able to fund their intangible investments from their
9
10 internal capital markets. These findings offer further support for *H2*.

13 Finally, the influence of financing from a prior equity issue on the intangibles-delisting nexus is
14
15 considered. Reese and Weisbach (2002) find that firms raise a substantial amount of equity following
16
17 cross-listings in the US, which helps them to build up a pool of reserves to fund future projects.
18
19 Accordingly, *H2* predicts that prior equity issues should reduce the net benefits of remaining listed,
20
21 and thus increase the likelihood for such firms to delist when they carry high intangible assets. The
22
23 results in Model 6 support this conjecture, with a positive and significant positive coefficient for the
24
25 interaction term (IAR*Seasoned equity offerings) (coefficient=0.071; *p-value*=0.005). This implies
26
27 that when firms are likely to have a pool of equity capital from past equity issues, they are more likely
28
29 to delist from stock markets when they have high levels of current intangible investments.
30
31
32
33
34

35 Taken together, the results in Table 6 generally support the predictions of the proposed theoretical
36
37 framework for this study which incorporates uncertainties in markets and valuation difficulties
38
39 associated with intangible assets with the generic cost-benefit theoretic framework of studies such as
40
41 Bharath and Dittmar (2010) and Chaplinsky and Ramchand (2012). That is, the information
42
43 asymmetry associated with intangible assets increases (reduces) the costs (net benefits) of remaining
44
45 listed for firms with high levels of intangible investments. Thus, such firms tend to delist from the
46
47 stock markets to protect their shareholders from losses, especially when they have alternative and
48
49 potentially less costly ways of financing their intangible investment projects.
50
51
52
53
54
55
56
57
58
59
60

6. Conclusion and implications

Unlike current studies on the motives behind firms' delisting decisions, which tend to focus largely on firms in developed economies and often ignoring the role of intangible assets, this study examines the predictive effect of intangible investments on corporate delisting decisions. In addition, it seeks to ascertain whether alternative sources of financing (other than raising new equity from the stock exchange) have a moderating effect on the intangibles-delisting nexus. A peculiar feature of the paper is that it is conducted within the context of Chinese firms listed on US markets and focused on delisting announcements made during the recent period of 2010-2016. This period is characterised by heightened uncertainty in US stock markets over Chinese public firms due to a series of accounting fraud allegations made against Chinese public firms by US analysts. Given that intangible assets attract more analyst coverage/attention, and are associated with greater analyst forecast errors, as well as present managers with opportunities to manipulate financial statements, US-listed Chinese firms with large amounts of intangibles risk having their shares mispriced/undervalued and incurring significant losses. All else equal, such firms acting reasonably should have a greater incentive to delist from the stock market.

Based on probit regression analysis controlling for a number of variables and year fixed-effects, and insights drawn from the asymmetric information and cost-benefit theories of listing, the results are summarized as follows. Firstly, the results suggest that investment in intangible assets is a strong predictor of corporate delisting decisions for emerging market firms cross-listing on stock exchanges in advanced countries. This implies that emerging market firms with large intangibles do face additional listing costs on advanced markets when there is greater market uncertainty relating to accounting fraud. Secondly, the finding indicates that the relationship between intangible assets and

1
2
3 the likelihood for emerging market firms to exit advanced stock markets is contingent on the
4
5 availability of alternative funding sources, particularly internal funding and prior equity issues. More
6
7 specifically, the results show that the positive impact of intangibles on firms' probability to delist is
8
9 higher for larger firms with greater internal capital market, more listing years, and more reserves built
10
11 up from prior seasoned equity issues. Thus, without surplus internal funds, high-intangibles emerging
12
13 market firms cross-listing on advanced markets may be forced to accept significant shareholder losses
14
15 in periods of greater market uncertainty. The interpretation and implications of our results are largely
16
17 consistent with expectations of the theoretical framework, which is based on insights from the
18
19 asymmetric information, and cost-benefit theories of listing.
20
21
22
23
24

25 We make new contributions to the existing literature. Specifically, we contribute to the debate on
26
27 the motivations behind the recent wave of delisting by Chinese firms from US markets by providing
28
29 evidence to suggest that the reportage of US analysts on accounting fraud involving Chinese public
30
31 firms may have increased the cost of remaining listed for firms with high investments in intangible
32
33 assets. An implication of the finding is that in periods of high market uncertainty, firms with a
34
35 significant investment in intangible assets risks destroying shareholders' wealth if they remain listed
36
37 on the stock exchange. Given the importance of intangible investments in promoting innovation and
38
39 economic growth, this finding should be worrisome to policy makers. Accordingly, policy makers and
40
41 standard setters must continue to work to improve the accounting regulations of intangible assets and
42
43 to promote the adoption of global accounting standard across both emerging and advanced economies.
44
45 Another key finding of the study is that the presence of alternative sources of funding helps to
46
47 mitigate the listing costs in turbulent times. An important implication flowing from this finding is that
48
49 public firms planning huge investments in intangibles should build up a reserve of internal funds as a
50
51
52
53
54
55
56
57
58
59
60

1
2
3 hedge against any increased future costs of remaining listed should the market become more
4
5
6 turbulent. Not having any funding reserves appears to leave public firms with no option but to remain
7
8 on the stock exchange and reluctantly accept the underpricing of their shares. Therefore, market
9
10 participants must keep an eye on the internal reserves of those public firms with huge investments in
11
12 intangibles.
13
14

15
16 Finally, inasmuch this paper makes important extensions to the literature, it is based on a limited
17
18 sample and the specific context of Chinese firms listed on US markets during a period of heightened
19
20 uncertainty due to accounting fraud allegations. Therefore, generalising the results outside this context
21
22 should be done cautiously. Further studies could offer additional insights by utilizing a larger sample
23
24 that considers several cases of accounting fraud allegations across countries over time for an analysis
25
26 that will permit generalisation to a larger extent. In addition, the focus of this paper did not extend to
27
28 the valuation implications of the delisting firms, making it unclear whether the market considers
29
30 delisting by high-intangible firms to be the “best” (value-enhancing) decision. This could again serve
31
32 as a potential avenue of future research, which could utilise event-study methodologies to examine
33
34 this issue.

Figure 1 - The number of Chinese firms listing on US stock markets from 1992-2016

Table 1: Sample distribution by industry and stock exchange

Industry	Stock exchange				Total
	AMEX	NASDAQ	NYSE	Other OTC	
Daily consumer products		3	3		6
Energy			1	1	2
Finance		1			1
Healthcare	1	6	5	1	13
Heavy industrial		3	3		6
Information technology		29	9	2	40
Materials		3	1	1	5
Optional consumer products		8	5	2	15
Public utility				1	1
Real estate			2		2
Total	1	53	29	8	91

Table 2: Annual sample distribution by delisting and listing years and number of listing years

Year	Number of firms by delisting and listing		Listing years and number of firms	
	Delisting	Listing	Listing years	Number of firms
2000		2	+1	9
2003		1	+2	10
2004		5	+3	16
2005		5	+4	13
2006		6	+5	15
2007		24	+6	4
2008		3	+7	5
2009		11	+8	8
2010	6	17	+9	5
2011	14	8	+10	1
2012	24	2	+11	2
2013	7	2	+12	2
2014	4	5	+14	1
2015	30		Total	91
2016	6			
Total	91	91		

Delisting represent Chinese firms announcing privatisation from US markets during 2010-2016. Listing refers to firms undertaking IPOs. Listing years refer to the period between the IPO date and the delisting date.

Table 3: Variable definition

Variables	Descriptions	Proxy for:	Sign
Market-to-book ratio (M/B)	Market capitalisation / total asset	Growth prospects/underpricing	-
Listing years	Number of days between IPO date and delisting announcement date / 365	Market knowledge or experience / alternative financing source	-/+
Intangible asset ratio (IAR)	Intangible assets / total assets	Intangible investments/asymmetric information	+
Free cash flow (FCF)	Free cash flow / total assets	Agency costs/alternative financing source	+
CEO duality	A dummy equal to one if firm has the same person occupying the positions of CEO and Board Chairperson, and zero otherwise	Agency costs	+
Capital expenditure intensity (CAPEX)	Capital expenditure / total sales	Growth prospects	-
Financial leverage (LEV)	Total debt / total assets	Alternative financing source	+
Seasoned equity offerings (SEO)	A dummy equal to one if the company raised equity capital after its IPO but prior to delisting, and zero otherwise.	Alternative financing source	-/+
Operating profit growth	Average of annual growth rate for operating profit for the last 3 years	Growth prospects	+
Return on equity (ROE)	After-tax profit / equity	Profitability/alternative financing source	+
Net assets per share	Net assets / number of shares	Growth prospects	-
Firm size	Natural log of total assets	Internal capital market/alternative financing source	+

Table 4: Descriptive statistics and correlation matrix

Panel A: Descriptive statistics

Variables	Full sample		Delist sample (D)		Control sample (C)		Difference (D-C)

The dependent variable takes a value of one if a firm publicly announced its decision to delist, otherwise zero. All other variables are defined in Table 4. Robust standard errors are utilised in the probit regressions. ***, **, and * indicate statistical significance of 1%, 5%, and 10% respectively.

The dependent variable takes a value of one if a firm publicly announced its decision to delist, otherwise zero. All other variables are defined in Table 4. Robust standard errors are utilised in the probit regressions. ***, **, and * indicate statistical significance of 1%, 5%, and 10% respectively.

¹As discussed in Pour and Lasfer (2015), a voluntary delisting is one that is initiated by a firm upon agreement with its shareholders (concurring votes from 75% of shareholders at a general meeting).

²Intangible assets are more difficult to value resulting in high information asymmetry between firms and investors (see Anagnostopoulou's (2008)'s review). International Accounting Standard (IAS) 38 sets out the recognition and measuring criteria, as well as, the disclosure requirements for intangible assets, defined as identifiable non-monetary assets without physical form. Examples of intangible assets include computer software, licenses, trademarks, patents, copyrights, goodwill, research and development (R&D) expenditure, etc.

³The few available Chinese studies are either theoretical in nature or based on single case study analysis, thus, lacking empirical analysis to provide persuasive evidence to

1

8 ⁵Orient Paper Inc. (ONP) forms part of our control sample for the empirical analysis. ONP listed on the New York Stock Exchange on 17th December 2009 and remained
9 listed as at the time of our data collection.

10 ⁶Detailed report can be obtained from this link: http://www.mmt.gov.hk/eng/reports/Evergrande_Report.pdf

11 ⁷iMeigu (<http://www.imeigu.com/>), Hexun (<http://www.hexun.com/>), and Sina Finance (<http://finance.sina.com.cn/stock/usstock/>).

12 ⁸The *Wind* financial database is a leading source of economic and financial data on China and Chinese firms. It integrates the most comprehensive and accurate market data,
13 fundamental data, research, news, and analytics tools across all asset classes in China, and provides investment professionals with the data and insights they need to
14 understand China's complex capital markets and economy.

15 ⁹These include the New York Stock Exchange (NYSE), American Stock Exchange (AMEX), National Association of Securities Dealers Automatic Quotation System
16 (NASDAQ), and other Over the Counter (OTC) markets.

17 ¹⁰Dropping firm size as a control variable from the regression model did not change our results and conclusions qualitatively. We decide to include it to limit the possibility of
18 omitted variable problems. More so, models including the firm size variable seemed to have higher explanatory power (as indicated by the Pseudo R-square statistic)
19 compared with those without firm size.
