Abstract

(Quantitative) structure-activity relationships ((Q)SARs) are widely used in chemical safety assessment to predict toxicological effects. Many thousands of (Q)SAR models have been developed and published, however, few are easily available to use. This investigation has applied previously developed Findability, Accessibility, Interoperability, and Reuse (FAIR) Principles for in silico models to six published, different, machine learning (ML) (Q)SARs for the same toxicity dataset (inhibition of growth to Tetrahymena pyriformis). The majority of principles were met, however, there are still gaps in making (Q)SARs FAIR. This study has enabled insights into, and recommendations for, the FAIRification of (Q)SARs including areas where more work and effort may be required. For instance, there is still a need for (Q)SARs to be associated with a unique identifier and full data / metadata for toxicological activity or endpoints, molecular properties and descriptors, as well as model description to be provided in a standardised manner. A number of solutions to the challenges were identified, such as building on the QSAR Model Reporting Format (QMRF) and the application of QSAR Assessment Framework (QAF). This study also demonstrated that resources such as the QSAR Databank (QsarDB, www.gsardb.org) are valuable in storing ML QSARs in a searchable database and also provide a Digital Object Identifier (DOI). Many activities related to FAIR are currently underway and (Q)SAR modellers should be encouraged to utilise these to move towards the easier access and use of models. Enabling FAIR computational toxicology models will support the overall progress towards animal free chemical safety assessment.

Plain language summary

This study relates to the availability of computational (termed *in silico*) models to predict the harmful effects of substances from a knowledge of chemical structure alone. The specific models referred to are (quantitative) structure-activity relationships ((Q)SARs, which have developed for many endpoints. Six machine learning models for toxicity were assessed against existing principles intended to make (Q)SARs findable, accessible, Interoperable and reusable (the FAIR principles). Evaluation of existing models against the FAIR principles highlighted a number of areas where progress is required to ensure the (Q)SARs are available for use. Currently there is no standard means to store (Q)SAR or provide a unique identifier, although the QSAR Databank (QsarDB) was illustrated as one possible solution. It is also crucial record the meta data associated with a model, such that it may be reproduced. A standardised ontology is required to facilitate the effective and accurate story of models and data.

1 Introduction

(Quantitative) structure-activity relationships ((Q)SARs) offer a means of making predictions of biological activity, physicochemical or pharmacokinetic properties from chemical structure alone. There is a particular need for, and focus on, the use of (Q)SARs with regard to animal-free chemical safety assessment, coming under the umbrella of "computational toxicology" (Madden et al., 2020). These models can include approaches to predict adverse outcomes (AOs), molecular initiating events (MIEs) and key events (KEs) from Adverse Outcome Pathways (AOPs), as well as toxicokinetics and other properties (Cronin et al., 2022). As such, computational toxicology is an essential part of frameworks and strategies such as Integrated Approaches for Testing and Assessment (IATA) (Laroche et al., 2019) and Next Generation Risk Assessment (NGRA) (Yang et al., 2023), which aim to make risk and hazard assessment decisions based on various levels of information relating to exposure and hazard. (Q)SARs, in particular, have found use in applications from rapid, high throughput, screening of molecules within inventories, through to providing lines-of-evidence to support an overall weight-of-evidence (Barber et al., 2024a). As such, (Q)SARs and other computational methodologies are a key New Approach Methodology (often termed computational or in silico NAM, meaning both computer simulations and computational models mimicking experiments or processes of physical laboratory work) and essential in non-animal chemical safety assessment (Westmoreland et al., 2022). Thus, the appropriate use of (Q)SAR and related technologies is seen as a fundamental components in the "3Rs" (Replacement, Reduction, and Refinement) relating to animal testing in chemical safety assessment (Laroche et al., 2019). Specifically, (Q)SAR models have been demonstrated to have applicability to make predictions relevant for regulatory purposes (Bishop et al., 2024) and are applied in a variety of chemical legislations as alternatives to animal testing, one example being the European Union (EU) Registration, Evaluation, Authorisation and restriction of CHemicals (REACH) regulation (ECHA, 2023).

The first use of the term "QSAR" is credited to Profs Hansch and Fujita and colleagues (Hansch et al., 1964). It is acknowledged, however, that the appreciation of a relationship between chemical structure, properties, descriptors and biological activity was known for over a century before modern definition of QSAR (Dearden, 2016). During their evolution, (Q)SARs have developed from the analysis of small data sets, either graphically or with linear regression analysis, through to the most recent approaches in machine learning (including recently deep learning) and other areas of artificial intelligence (Madden et al., 2020).

For use in chemical risk assessment, it is acknowledged that a (Q)SAR must fulfil established criteria for validity, such as the Organisation for Economic Cooperation and Development (OECD) Principles for the Validation of (Q)SARs (OECD, 2007). The OECD Principles are the basis of the QSAR Model Reporting Format (QMRF), which provides a means of the textual documentation of a (Q)SAR (OECD, 2023b). From 2023, the OECD-adopted QMRF is part of the QSAR Assessment Framework (QAF), which has provided a means of documenting and assessing a prediction from a (Q)SAR, with a view to understanding uncertainties within the prediction (OECD, 2023a; Gissi et al., 2024; Barber et al., 2024b). Whilst these methods, in addition to copious guidance from international agencies, provide a means of assessing models, it has been proposed that models should also adhere to the Findability, Accessibility, Interoperability, and Reuse (FAIR) Principles (Wilkinson et al., 2016), originally intended to guide scientific data management and stewardship.

For a (Q)SAR to have practical application, it must be retrievable and usable. There are an unknown number of (Q)SARs in the published literature, possibly thousands of models across a myriad of endpoints. Most of these are, in reality, not usable (Piir et al., 2018). There are many reasons for the non-functionality of the majority of published models. For instance, whilst the QMRF provides a means of describing the model not all modellers have adopted use of the QMRF. A full, interpretable and transparent description of the model is not provided for many models, particularly those that precede the development of the QMRF. Neither is there a standardised method to store, search for and retrieve (Q)SARs. This suggests both a missed opportunity to use computational toxicology models, but also insufficient attention and support by the modelling community and their practices to ensure the sustainability of their models.

In response to the issues related to making (Q)SAR models sustainable and usable, the existing principles to enable scientific data to be FAIR (Wilkinson et al., 2016) were adapted by Cronin et al. (2023). Eighteen FAIR principles for *in silico* toxicology models were proposed with the intention that they would allow models to be more usable, with a particular focus on improving regulatory applicability and acceptance. In addition, a number of resources were identified that may assist in making (Q)SAR models, in particular, FAIR. There are only limited resources that may be applied to make (Q)SAR models available, notable amongst these are the JRC QSAR Model Database (EC, 2020); BioModels (Glont et al., 2018; Malik-Sheriff et al., 2020); Harvard Dataverse¹; the Danish (Q)SAR Database²; the ConcertREACH Gateway for predictive computational (QSAR) toxicology models³ and the QSAR DataBank (QsarDB) repository from the University of Tartu, Estonia (Ruusmann et al. 2015). Of these, the JRC QSAR Model Database is a static and historic resource, which only allows downloads of QMRF documentations of models, and the Harvard Dataverse and BioModels contain a paucity of (Q)SAR models. The Danish (Q)SAR Models web application that contains in-house models. The ConcertREACH Gateway provides details of available software for toxicity prediction and links to the models. The QsarDB⁴ provides a platform with the potential to meet many of the criteria of the FAIR principles i.e., it is searchable in terms of chemistry, endpoint etc. It is robust, interoperable and provides access to (Q)SARs in a FAIR manner.

Further to limited resources for ensuring availability of (Q)SAR models, little is known about the FAIRness of existing (Q)SAR models for toxicity, especially those employing more complex modelling approaches, such as neural networks. The aims of this investigation were to evaluate existing (Q)SAR models for toxicity, according to the previously

³ https://www.life-concertreach.eu/results/results-gateway/

⁴ https://qsardb.org/

published FAIR principles (Cronin et al., 2023) and identify areas where improvements are needed. The models chosen for assessment were six machine learning (ML) models developed on a single dataset and published previously by the first and corresponding authors of this manuscript (Belfield et al., 2023). From the analysis of these six existing models, a series of recommendations to promote the FAIRness of (Q)SAR models for toxicity have been established.

2 Materials and methods

2.1 Retrieval of (Q)SAR models

Six machine learning QSAR models were selected for evaluation, these were obtained from Belfield et al. (2023). The models were selected on the basis of being freely available, representing a variety of machine learning approaches and had reasonable performance, with comparatively well-understood data quality and mechanistic interpretability. In short, these models utilise six different ML algorithms (Random Forest, XGBoost, Support Vector Machine, k-Nearest Neighbors, Neural Network, and Deep Neural Network) to predict *Tetrahymena pyriformis* growth inhibition.

2.2 Evaluation of (Q)SARs according to FAIR Principles

Models were assessed following the previously reported FAIR principles for *in silico* models (Cronin et al., 2023) with each principle being assessed qualitatively, accompanied by the rationale for the assessment, as well as potential strategies for improving adherence to the FAIR principles, where appropriate. Due to the development and approach for each model being identical, (except for the machine learning algorithm employed) models were evaluated against the FAIR principles as a singular set of models.

2.3 Uploading models to the QSAR databank

(Q)SAR models were incorporated into the QsarDB. To achieve this, the original QSAR models were reproduced with the code from Jupyter notebooks in GitHub⁵ and converted into Open Neural Network Exchange (ONNX) standardised format using the open-source Python library onnxmltools (version 1.11.2), based in part on the information collected by the QMRF. This conversion step is crucial for maintaining compatibility across various platforms and facilitating the integration of models into diverse software environments. It is acknowledged that conversion to ONNX from an original format may alter the original model, so there is a need to check the performance and statistics of the model. In addition, the ONNX capture does not necessarily go beyond or replace the QMRF, but allows for a workable version of the model to be stored. Models in ONNX then became an integral part of the QsarDB data format. This involved preparing comprehensive metadata that describes the models' purpose, methodology, the specific endpoints it predicts and complete structural data to derive and validate model. The platform assigns a Digital Object Identifier (DOI) to the uploaded model, which serves as a permanent identifier. Appropriate licensing options were selected i.e., Creative Commons licenses, which clarify the terms of use for the model.

3 Results and discussion

3.1 Evaluation of the six (Q)SARs for toxicity according to the FAIR principles

18 principles have been developed and adapted for *in silico* models covering all aspects of the FAIR concept (Cronin et al., 2023). Each of the individual principles provides guidance and considerations for developers that, once adhered to, will foster a model that has been produced, labelled, and stored in a manner that fully promotes shareability and can be categorised as FAIR. Evaluation of models through application of the FAIR principles can highlight issues within a given workflow, which in turn may be hindering shareability. This study investigated the ability of the principles to be utilised in this manner to provide practical information on the models with regard to whether they are FAIR, allowing for recommendations to be made.

The ability of the six previously developed machine learning models (Belfield et al., 2023) to satisfy the FAIR criteria is summarised in Tables 1-4. In total, 20 FAIR criteria were considered due to two of the original 18 FAIR principles (F2 and A1) having two parts. As the development of each model was identical, and only differing dependent upon algorithm utilised, all models were evaluated together as a single set. To this end, each principle was considered individually and a verdict recorded as to whether or not the principle was met (yes, no or partially) with the accompanying reasoning also being recorded for transparency. As seen in Tables 1-4, the majority (eleven of twenty) of principles are reported to be sufficiently satisfied; however, six principles were not met, and the remaining three principles met only partially. Whilst the successes outweigh the failures it is essential that, for a model to be considered FAIR, all principles are sufficiently satisfied. As this was not the case, strategies for improvement were suggested where appropriate.

The assessment of the models with regard to the Findable principles is summarised in Table 1. The Findable principles relate, in part at least, to the ability to search for and retrieve a particular (Q)SAR, as well as it being adequately described. These principles are fundamental to being able to find relevant (Q)SARs for a particular purpose. When assessed in terms of being findable, the previously published models were found lacking due to the absence of unique identifiers and provision of adequate metadata. Currently, there is no agreed and accepted unique identifier for a (Q)SAR, and most identifiers relate simply to the description of the model, which is represented without using any standard format. A proposed solution to this issue would be the allocation of a DOI, as it is a well-established standard for publications and other items. Whilst the DOI is non-descriptive, it is a globally unique and definitive identifier that can be directly accessed or searched for with an

⁵ Datasets and Python source code employed for and in the processes of model construction, optimisation and performance assessment for models evaluated in the manuscript by Belfield et al. 2023. https://github.com/LJMU-Chemoinformatics/Best-Practice-Supplementary (accessed 14. November 2024)

2025/101 being Tindable and	associated improvement strategies	
FAIR Principle (from Cronin et al., 2023)	Verdict and reasoning	Comments, examples and improvement strategies, where applicable if FAIR Principle not met
F1. Each model is assigned a globally unique and persistent identifier and different versions are assigned distinct identifiers.	No. Models have only been assigned local identifiers that are associated throughout development. These identifiers are descriptive but would not be suitable for searching or cataloguing.	There is a clear need for the models to be assigned a unique global identifier such as a DOI. This would enable cataloguing and searching for the model.
F2. Models are described with rich metadata covering all aspects of the model.		
F2.1. Models are associated with searchable metadata for the property or endpoint to be predicted.	Yes. Models are developed with searchable metadata for the endpoint of interest which is publicly available.	All the data used in model development are available on Github ⁵ as comma separated (.csv) files. This includes appropriate annotation and description of variables.
F2.2. Models are associated with searchable metadata or descriptions of the chemicals (e.g. InChI or SMILES), or chemical class(es), within the model, or a description of its applicability domain.	Partially. Unique chemical identifiers (CAS numbers, IUPAC name) are provided for each chemical in the metadata abd used within the model. However, applicability domains were not defined with the exception that descriptor ranges could be identified.	Models need to be associated with a clearly defined applicability domain. It is noted that applicability domain may vary with different model types, so would need to be defined for each machine learning QSAR.
F3. Models' (meta)data clearly and explicitly include the identifier of the model they describe and are registered or indexed in a searchable resource.	No. The metadata associated with the model (its identifier(s)) is minimal, providing only sparse information regarding the algorithm and data utilised. The type of ML model is described, but the model itself is not articulated.	Models should be associated with appropriate identifier(s) that describe the key characteristics including endpoint, modelling approach and type of data.
F4. Models are registered or indexed in a searchable resource.		
F4.1 Models' identifiers should be optimised to allow for use in multiple search engines.	No . The identifiers of the models are not available in a searchable resource.	Once the identifiers are established, they need to be stored within a searchable resource. A minimum is the provision of a DOI, but also description of the endpoint, e.g., species, test, duration, in addition to the types of chemicals tested e.g., small organic molecules (non- pharmaceutical / biocide). Information on putative mechanisms of action may also be helpful.

Tab. 1: Assessment of the set of six machine learning QSAR models with regard to the FAIR Principles (Cronin et al., 2023) for being "Findable" and associated improvement strategies

internet search engine. This identifier should also allow for the QSAR model to be findable even if it's physical location changes.

There is also a need to standardise the description of the type of model and data contained within the model, for instance, building on the QMRF as implemented in the QAF. This could include a formalised approach to reporting, describing and providing the dependent and independent data, as well as the modelling approach. Standardisation of model reporting is crucial for ML approaches where terminology and descriptions can vary. In terms of making (Q)SARs "Findable", this would assist in being able to use standard terms that could be searched for, e.g. a particular endpoint, species or type of (Q)SAR model. For a (non-commercial) model to be reproducible, there are a large number of pieces of information that need to be gathered and stored, especially relating to the creation of the model (see Cronin et al. (2023) and Piir et al. (2018) for details). In addition, there is an overwhelming requirement to provide and store the applicability domain of a model. However, the applicability domain can be defined in a number of ways (Dimitrov et al., 2005; Netzeva et al., 2005), and may provide different metrics even for the same data sets when modelled with different approaches. Applicability domains can be calculated automatically according to the OECD (Q)SAR Validation Principles if full data about model are available (see the realization in QsarDB repository for regression models).

The second assessment of the QSAR models is in terms of their being "Accessible" (Table 2). The models assessed were published (Belfield et al., 2023) and the (meta)data (for endpoint and descriptors) and Jupyter notebooks for reproducing the models are made available via GitHub⁵, thus in this instance the models can be considered meet the FAIR principles for accessibility. It should be noted, however, that whilst the model and its description are available, this does not imply that there is a functional model that could be used to make a prediction. In addition, there may be limitations in the size of the model and associated data that can be stored, especially if free-to-use resources are utilised.

The assessment of the QSAR models in terms of their "Interoperability" is summarised in Table 3. Whilst the machine learning models and metadata in this study were well described, there is no comprehensive and standardised ontology

Tab. 2: Assessment of the set of six machine learning QSAR models with regard to the FAIR Principles (Cronin et al., 2023) for being "Accessible".

FAIR Principle (from Cronin et al., 2023)	Verdict and reasoning	Comments, examples and improvement strategies
A1. Models are retrievable by their identifier using a standardised communications protocol.		
A1.1. The model (and any associated protocol represented by the model metadata) is openly accessible or reimplementable.	Yes. Models are openly accessible and stored within a public repository on GitHub from where they could be reimplemented.	The models are available on Github as ipynb files which can be executed in a Jupyter notebook. As required, all data are also available as .csv files, thus the models can be reimplemented and reproduced.
A1.2. The model (and any associated protocol) allows for an authentication and authorisation procedure, where necessary.	Yes. Models' full development are publicly available and GitHub platform implements access control mechanisms to protect this data from unauthorized changes.	In this context, GitHub implements access controls.
A2. Model (meta)data are accessible even when the model is no longer available, unless restricted for commercial, ethical or data protection reasons (e.g., blinding of confidential chemical structures).	Yes. Metadata are openly accessible and stored within a public repository on GitHub. However, the completeness and quality of the metadata should be assured.	There were no restriction, e.g. business confidentiality or ethical, on the data. Therefore, all data are available. There are instances where the metadata could be more comprehensive, e.g., in describing the endpoint and descriptors in detail.

Tab. 3: Assessment of the set of six machine learning QSAR models with regard to the FAIR Principles (Cronin et al., 2023) for being "Interoperable" and associated improvement strategies.

et al., 2023)	Verdict and reasoning	comments, examples and improvement strategies, where applicable if FAIR Principle not met
I1. The models and their (meta)data are described in a standardised manner, i.e., standards to define chemical structures, endpoints, molecular descriptors and modelling algorithms.	Yes. Models and their metadata are described and annotated. The data are described with terminologies for e.g., endpoint, descriptors, that are well defined and commonly used, whilst not officially standardised, e.g. in an accepted ontology. The model and data description are located within the associated documentation to URLs for the models in QsarDB as noted in Table 5.	Whilst this Principle is met, it may be optimal to align the description with other accepted formats such as applied QMRF / QAF templates and QDB archive (Ruusmann et al. 2014). This principle also emphasises the requirement for standardised approaches to all elements of a (Q)SAR.
12. The model reads, writes and exchanges data in a way that meets domain-relevant community standards.	No. Models exchanging of information did not follow domain-relevant community standards such as QMRF or QAF	Community standards could be utilised, for instance those developed for QMRF, QAF, OpenTox (Hardy et al., 2010; 2012). At the current time, there is a paucity of community standards, so the model developer should use what is currently best practice within, e.g., QMRF, QAF etc.
13. The model must be interoperable with other software, e.g., with a clearly defined input/output i.e., with an appropriate Application Programming Interface (API) for shared web services.	Partially . Clearly defined inputs and outputs for the models are outlined; however, no standardised, well-documented output for interoperability exists for them currently.	Models need to be machine actionable, i.e., further developed with clear consideration for how interoperability could be achieved e.g., for shared web services. This will be essential to implement the models, make them available for e.g., tiered testing strategies and / or atomisation.
I4. (Meta)data use a formal, accessible, shared, and broadly applicable language for knowledge representation.	Partially . Metadata are described using well utilised, although not always accepted identifiers.	Identifiers need to be standardised, for instance aligning with QMRF, QAF. This will enable others to understand and utilise the model.
I5. (Meta)data use vocabularies that follow FAIR principles.	Yes. Meta data adhere to the FAIR principles and are provided in .csv files on Github.	As well as being good practice, this will form the basis rational methods to search for the model, i.e., standardised search terms for endpoint, model type, number and type of descriptors etc.
I6. The model includes qualified references to other objects, such as molecular descriptors.	Yes. Objects outside of the original metadata that have been produced are appropriately referenced to original sources with the information additionally being publicly available.	The other objects in the models are the molecular descriptor set. Not only are the descriptor values given, but the software is named. Since the chemical identifiers are provided, if required, the descriptors could be recalculated, updated or extended.

generally accepted for describing QSAR models, descriptors, performance statistics, etc. However, some efforts could be built upon and developed further to help resolve this issue, such as the OpenTox framework (Hardy et al., 2010; 2012), OntoQSAR (Angelo et al., 2020), work towards interoperable QSAR datasets (Spjuth et al., 2010), Chemical Information Ontology (Hastings et al., 2011), QSAR descriptor ontologies (Floris et al., 2011;⁶ and others). The other key area to make QSAR models fully interoperable is to allow the models to communicate with other software, for instance, with an Application Programming Interface (API) or standard output format.

FAIR principles for QSARs should also incorporate the concept of machine actionability (Principle I3). Wilkinson et al. (2016) used the term "machine actionable" to be a continuum whereby a digital object provides increasingly more detailed information to an autonomously acting, computational resource that intends to utilise the data. Further, being "machine actionable" means that if a computational resource approaches data it has not seen before, it is able to determine what the data (or object) are, the potential use of the data or object for the intended purpose, assess usability with regard to licences etc., and take appropriate action. FAIR QSARs being machine actionable indicates that other computational resources are able to use data (both the activity modelled and descriptor set) and models automatically. This was a principle demonstrated within the OpenTox framework (Hardy et al, 2010; 2012) and should allow data to be made available for purposes such as the automatic evaluation, development and extension of QSAR models. For this purpose, APIs can provide easy computational access to resources and for FAIR data and knowledge use. However, there are a number of caveats that should be borne in mind with regard to machine actionable APIs in QSAR development. This is an area where standardised vocabularies and ontologies are crucial, to enable a third party computational resource to access and utilise data. In addition, at least in the short term, there may be a requirement for human intervention in areas such as interpreting and assessing data reliability and quality.

The assessment of the QSAR models for being "Reusable" is summarised in Table 4. The models published by Belfield et al. (2023) were generally reusable, although specific information, such as the lack of a licence for use, was absent. Again, this FAIR principle emphasises the need for the better use of a standard ontology. There may also need to be greater consideration of how third party software may be versioned and would be available for later use. For instance, if software is used to calculate descriptors, will need to be available for the future application of the (Q)SAR model. This may require that the model storage utilises robust and sustainable software, or that descriptors can be obtained by other means while still providing the same values.

The reusability of a (Q)SAR should, ideally, go beyond simply downloading and using the model to make further predictions. Should the metadata and characteristics of the model be available undefined, then it should be possible to recalculate, or recalibrate, a model. This would be highly valuable to ensure the model is reproducible and inevitably requires that the metadata are available for use. Having the (meta)data available also means that the model can be redeveloped, for instance if there is information regarding mechanism of action or possible outliers, poor quality data etc. The model can also be extended through enrichment of the training data set or descriptor set. For instance this may become possible should further data become available or more testing is undertaken. Thus, re usability is a vital characteristic within the FAIR criteria and this will allow for improved and extended models to be developed in the future, providing full metadata and description of the model is given.

3.2 Use of QsarDB to reduce non-compliance with FAIR Principles

In order to resolve the non-compliance with the FAIR Principles, the models were entered in the QsarDB (Ruusman et al., 2015). QsarDB provides a means of organising and archiving (Q)SAR models into QDB archive format (Ruusman et al., 2014). The structured approach to integrating (Q)SAR models into the QsarDB platform not only enhances the usability of these models but also promotes their sustainability and accessibility for future research in computational toxicology. By ensuring compatibility, providing rich metadata, and assigning permanent identifiers, the QsarDB platform contributes to the advancement of (Q)SAR research and its applications in various fields. At the time of writing this manuscript, QsarDB contained over 550 QSAR models. The models entered into QsarDB are given a unique identifier (a DOI) and can be used for data citations; Table 5 summarises the DOI and citation information for the models considered in this investigation that were originally reported by Belfield et al. (2023).

The storage of the models in QsarDB enabled a number of issues with the non-compliance of FAIR Principles to be resolved. QsarDB is dedicated to making (Q)SARs machine readable, interactive, predictive and ultimately FAIR. It has received the CoreTrustSeal meeting the requirements for trustworthy data repositories⁷. QsarDB enables not only the efficient storage of (Q)SAR models, but also allows the user to search for models by various criteria such as endpoint, species and chemistry and importantly allows visualisation of model content and also to perform predictions with models. The QsarDB approach also provides a number of technologies that assist in the resolution of the concerns raised in this investigation. For instance, the use of a DOI (e.g., as provided in QsarDB) provides a solution to the challenges raised with regard to F1, F3 and F4, providing a unique and permanent identifier. DOIs are ubiquitous in the scientific literature, they are designed to be searchable, e.g. within an internet search engine, which will increase the possibility of a (Q)SAR model being found. QsarDB also provides a means to communicate with selected software, with an API being available (Principle I3). It can also provide a license for use of a model (Principle R2) with models being made available under the Creative Commons license. QsarDB has also provided a means of standardising terminology with the platform (Principles I2 and R6), but this remains a significant issue for the broader (Q)SAR community. In other words, there is no formal agreement on community standards or ontology. QsarDB may also provide a sustainable platform for obtaining reliable descriptors and applying algorithms when other software may not be available.

It should be noted that QsarDB also supports uploading QMRF documents without fully disclosing the model, which helps the community by making documentation about commercial (Q)SAR models available. However, it is not the intention

FAIR Principle (from Cronin et	Verdict and reasoning	Comments, examples and improvement
ai., 2023)		Principle not met
R1. The model is available for use in some format (e.g., source code, executable, library or service).	Yes. The models are available for their intended use within an executable source code.	In this case, the models are available on Github as .ipynb files. Any similar approach or implementable file type would be suitable for this purpose.
R2. The usage license of the model should be clearly defined and appropriate to encourage its use.	No . No usage license for the models have been provided.	Models need to be accompanied by a usage licence, such as Creative Commons etc., that actively encourages their usage. Clear licencing, which can be achieved easily with Creative Commons, also established how and when the model can be used and whether it could be incorporated into further software / predictive toxicology tools.
R3. The storage of the model and (meta)data should be done on a sustainable and future-proofed platform, anticipating the impact on the availability of software changes over time.	Yes. Models and metadata are stored within a public repository on GitHub, which is globally accepted as a sustainable platform. It is appreciated that this can only be for a reasonable period time, though should be made as robust as possible.	The use of .csv files means the data can be converted into formats suitable for other modelling tools. As the standards for future file types and software are unknown, storing generic file types is recommended.
R4. Software includes qualified references to other software, e.g., so that the correct molecular descriptors can be obtained, either as part of the model or storage of the molecular descriptors software or experimental protocol.	Yes. All software used throughout the development of the models and production of descriptors for the metadata are accurately referenced in the associated publication. Software version numbers are included.	Whilst software assessed in this investigation is available and calculations could be repeated, there should be consideration of being able to store the software itself for future use e.g. for making predictions for chemicals at a later stage and outside of the model space.
R5. (Meta)data are richly described with a plurality of accurate and relevant attributes		
R5.1 The model and its (meta)data are associated with detailed provenance	Yes. The origins of the metadata are clearly provided, including version number, software provider, within the associated publication.	The metadata are clearly described with appropriate references.
R6. The model and its (meta)data meet domain-relevant community standards for documentation	No. Domain-relevant community standards for data documentation are unavailable.	Once community standards for data documentation are proposed such procedures must be adhered to. These could utilise and / or extend the headings utilised in the QMRF template. Community standards are required and will increase the FAIRness of (Q)SARs as well as making them more usable in the future.

Tab. 4: Assessment of the set of six machine learning QSAR models with regard to the FAIR Principles (Cronin et al., 2023) for being "Reusable" and associated improvement strategies.

of the FAIR principles that all models should be transparently disclosed. This would be restrictive for complex models, such as generative AI, but most specifically for commercial models where the commerciality of the model and / or data does not permit it to be revealed. Instead, for these models the FAIR principles intend to allow the model to be findable, described (as is possible with the QMRF) and identifiable.

Other resources do, of course, provide a means to store data and models. The large, cloud based, storage sites include Zenodo, GitHub, Figshare, etc. Indeed, GitHub was utilised by Belfield et al. (2023) to store information on the models⁵. Whilst they provide a (limited – in terms of file size) storage solution, they do not ensure compliance with all FAIR principles, i.e. they do not provide an intuitive and searchable resource or encourage application of standard ontologies or community standards. Some of these issues are resolved elsewhere, e.g. BioModels and Harvard Dataverse, however these are not designed to be bespoke to QSARs and have few representative models.

3.3 Importance of making QSARs FAIR

The FAIR concept has been applied broadly to data (Wilkinson et al., 2016) but also specifically in toxicologically-relevant areas. For example, Wittwehr et al. (2024) have demonstrated the importance of the FAIR principles to AOPs. Elsewhere, Ammar et al. (2024) developed a NanoSafety Data Reusability Assessment (NSDRA) framework to summarise the reusability of nanosafety datasets based on FAIR maturity indicators, including for human toxicity. Briggs et al. (2021) illustrated the benefits of data sharing for preclinical safety assessment in drug development following the FAIR principles, including reducing time spent curating, transforming, and aggregating datasets, allowing more time for data mining and analysis. Other

practical recipes on how to implement FAIR for real-world settings include the FAIR Cookbook8 created by biopharmaceutical and academic professionals, and guidance on data management practices, such as the RDMKit⁹, which highlight how FAIR principles are the backbone for the creation of open systems leading to improved reproducibility and quality of data. In addition, organisations such as the GO FAIR Foundation¹⁰ actively promote the interpretation and implementation of FAIR principles to data as well as community standards and training and tools to assess FAIR levels¹¹. It seems logical, therefore, that QSARs to support chemical safety assessment should be FAIR. This will enable models to be used across the community where ensuring (Q)SARs are reproducible, regardless of purpose, is essential. Reproducibility is particularly crucial with regard to regulatory assessment where a third party (for instance a governmental agency) may wish to replicate, or better understand, a prediction. There is also a duty to make models available, particularly when they have been funded from public resources and to make them sustainable. It should be remembered, however, that making a model FAIR does not imply all models should be open source - there is still a place for commercially sensitive models to be FAIR up to a level where commercial property is still protected but the necessary information is shared. For example, a model may be created using confidential information, which cannot itself be made publicly available. Alternatively, the model itself, or knowledge contained therein, maybe commercially important. The FAIR Principles do not imply that confidential knowledge and / or data, or intellectual property should be freely accessible, but rather that there is sufficient access to the model information in a searchable manner.

Consideration of the FAIR Principles in this investigation has revealed a number of key areas where improvements could be made. The first area is in the development of searchable databases to find relevant information and models. This would go beyond a simple internet, or literature, search as it could incorporate not only the endpoint, but also aspects of the chemistry, i.e. an intelligent search query could be to retrieve (Q)SARs "for a particular endpoint and a particular chemistry". Further, there is an opportunity to make, where there are no commercial or business restrictions, models transparent with data and algorithms presented according to relevant community standards. Means of capturing (Q)SARs are commonly applied, such as the QMRF (OECD, 2023b) which go a long way to providing a framework that could be built upon and extended. Other approaches include the proposal of the OpenTox Framework (Hardy et al., 2010; 2012). Whilst the OpenTox Framework predates the FAIR Principles it is closely aligned by providing an interoperable standards-based Framework supporting toxicology data management and reporting.

The implementation of the FAIR principles can utilise commonly applied means of capturing and evaluating QSARs (and their predictions). For instance, the OECD QAF (OECD, 2023a) requires information on not only the model, e.g., goodness of fit, and mechanistic interpretation, but also on the assessment of predictions themselves, such as reliability and fitness for regulatory purposes. QAF was recently adapted for multiple predictions informed by multiple QSARs (Gissi et al., 2024). Both QAF and FAIR are applicable irrespective of the modelling method used to build a model or the endpoint for which it was developed, which ensures real-world adoption. It is intended that the FAIR principles will go beyond the documentation required by QAF to allow for full data and the model to be made available within a searchable form. As

¹¹ https://www.fairsfair.eu/

acknowledged by Barber et al. (2024b), trusting an *in silico* model needs to be questioned before the output is used to support a regulatory decision. FAIR principles allow us to evaluate this aspect as well as encourage the development of open benchmarks to facilitate the testing and increase the validity of such models.

Enabling FAIR (Q)SARs will require resources to be made available. (Q)SAR developers who wish to support FAIR models can do so as part of the modelling process. However, key elements of FAIR will require physical, financial and intellectual input. A resource to store and distribute (Q)SARs, such as any of those mentioned in this article requires space on a hardware platform. The system requires funding for upkeep, maintenance and, as appropriate, training and dissemination. For robust sustainability, a reliable funding source is required with backup and contingency planning. Finally, intellectual input will be required in the creation and acceptance of community standards for topics such as ontologies. Utilising Working Groups, such as those at OECD, will enable uptake of the outputs, but will require appropriate resources, both financially and with regard to person months, and for member nations and other stakeholders to provide input.

3.4 Recommendations for making (Q)SARs FAIR

This investigation provides insights into making (Q)SAR models for toxicity prediction FAIR. There are considerable long-term benefits to this ambition, although for success, there needs to be global vision and uptake – this may only be possible with appropriate international agreement and collaboration.

- There should be a move towards FAIR (Q)SAR models, with a greater emphasis on understanding what this means, with a particular focus on how to make commercially or business sensitive models FAIR.
- (Q)SAR models should be created using machine actionable descriptors and algorithms that can obtained in the future, i.e., when the specific versions of software may have been retired or superseded.
- Sustainable, searchable databases are required to store and retrieve models, where one solution is QsarDB.
- There is a clear need for agreed community standards for reporting models, the underlying data and descriptors, as well as performance statistics. This could potentially include and develop further the QMRF.
- Journals and other means of reporting models should be encouraged to ensure that models are FAIR.
- The cost of providing sustainable and FAIR (Q)SAR models must be appreciated and budgeted for.
- Greater efforts should be made to ensure functional models are interoperable with other software to enable their use.

4 Conclusions

The study has evaluated some existing machine learning (Q)SAR models for toxicity according to previously published FAIR principles. There are a number of key areas where the QSAR models do not comply with the FAIR principles. The models lack a unique identifier, the full data and metadata were not presented and licenses for use of the models are not available. Such limitations can be overcome using existing resources such as QsarDB (amongst others). A fundamental area that will require more concerted effort will be the definition of community standards. It is clear that to retain credibility, (Q)SAR modellers should strive to make their models FAIR. However, addressing the concerns raised in this investigation will require a community effort to utilise current solutions and develop, where necessary, further solutions and allocation of resources.
